**Abstract**

The splitting of separatrices for Hamiltonians with $1\frac{1}{2}$ degrees of freedom

$$h(x, t/\varepsilon) = h^0(x) + \mu\varepsilon^p h^1(x, t/\varepsilon)$$

is measured. Here $h^0(x) = h^0(x_1, x_2) = x_2^2/2 + V(x_1)$ has an associated separatrix $x^0(t)$, $h^1(x, \theta)$ is $2\pi$-periodic in $\theta = t/\varepsilon$, $\mu$ and $\varepsilon > 0$ are independent small parameters, and $p \geq 0$. Under suitable conditions of meromorphicity for $x_2^0(u)$ and the perturbation $h^1(x^0(u), \theta)$, the order $\ell$ of the perturbation on the separatrix is introduced, and it is proved that, for $p \geq \ell$, the splitting is given in first order by the Melnikov function.

## 1 Introduction and main results

The effective measure of the splitting of separatrices of rapidly forced systems has been obtained by several authors [HMS88,GLT91,DS92,Ang93,Gel93,Tre94,Sau95], but, in general, for very specific examples.

For more general systems, upper estimates have been obtained in several papers [Nei84,Fon93,Sim94,Fon95,FS96], and more recently, asymptotic expressions or lower estimates [Gal94,Gel95,DGJS96,RW96].

The main feature of this kind of systems is that the splitting is exponentially small with respect to the parameter of perturbation, and consequently a direct application of the Melnikov method does not provide rigorous results.

Following the main ideas of [DS93,DS94], we want to present in this article a general method, with full details, to validate the asymptotic expressions given by the Melnikov function for general Hamiltonian systems with $1\frac{1}{2}$ degrees of freedom.

We shall consider a Hamiltonian of the form

$$h(x, t/\varepsilon) = h^0(x) + \mu\varepsilon^p h^1(x, t/\varepsilon),$$

where $h^0(x) = h^0(x_1, x_2) = x_2^2/2 + V(x_1)$, $\mu$ and $\varepsilon > 0$ are independent small parameters, and $p \geq 0$.

The Hamiltonian system associated to $h$ is a perturbation of the Hamiltonian system associated to $h^0$:

$$\dot{x}_1 = x_2, \qquad \dot{x}_2 = f(x_1), \tag{1.1}$$

where $f(x_1) = -V'(x_1)$, which can be written also as a second order equation

$$\ddot{x}_1 = f(x_1).$$

We will assume the following hypotheses:

*H1* The unperturbed system (1.1) has a saddle point at the origin with characteristic exponents $\pm\omega^0$, with $\omega^0 > 0$, and there exists a homoclinic solution $x^0(t) = (x_1^0(t), x_2^0(t))$ to this point: $x^0(t) \longrightarrow 0$ for $t \to \pm\infty$.

*H2* $f(x_1)$ is a real entire function, and $x_2^0(u) = \dot{x}_1^0(u)$ is analytic on a strip $|\Im u| < a$, with a pole of order $r$ at $u = \pm a\,\mathrm{i}$ as its only singularity on each line $\Im u = \pm a\,\mathrm{i}$.

*H3* $h^1(x, \theta)$ is $2\pi$-periodic and $\mathcal{C}^1$ in $\theta$, with zero mean: $\int_0^{2\pi} h^1(x, \theta)\,\mathrm{d}\theta = 0$. With respect to $x$, it can take the following forms:

(a) if $f$ is $2\pi$-periodic, $h^1$ is a trigonometric polynomial in $x_1$ and a polynomial in $x_2$; $h^1(x, \theta) = x_1 g(\theta)$ is also allowed,

(b) $h^1$ is a polynomial in $x$, in the case that $f$ is not $2\pi$-periodic.

As a consequence, $h^1(x, \theta)$ can be written as a sum of monomies in the variable $x$, each of them having a pole at $u = \pm a\,\mathrm{i}$, when $x = x^0(u)$, for every $\theta$. We will denote $\ell$ the greatest order of this pole among these monomies.

To state our results, let us begin by writing the Hamiltonian system associated to $h$:

$$\begin{aligned} \dot{x}_1 &= x_2 + \mu\varepsilon^p \partial_2 h^1(x, t/\varepsilon), \\ \dot{x}_2 &= f(x_1) - \mu\varepsilon^p \partial_1 h^1(x, t/\varepsilon). \end{aligned} \tag{1.2}$$

Due to the fact that system (1.2) is $2\pi\varepsilon$-periodic in time, we can consider the associated Poincaré map defined by:

$$P(x_0) = x(2\pi\varepsilon), \tag{1.3}$$

where $x(t)$ is the solution of system (1.2) that begins at $x_0$ when $t = 0$.

For $\mu = 0$, system (1.2) becomes autonomous and therefore the phase portraits of the Poincaré map $P$ and system (1.1) are identical. In fact, this phase portrait is filled up with the level curves of the Hamiltonian $h^0$. If we assume $V(0) = 0$, the homoclinic orbit $x^0$ is contained in the level curve $h^0(x) = 0$.

For $\mu \neq 0$ but small enough, the dynamics of system (1.2) becomes more intricate and the phase portrait of the Poincaré map $P$ changes. There exists a hyperbolic fixed point near $(0,0)$ whose stable and unstable curves intersect—$P$ is an area preserving map—but generically they do not coincide. We denote $x^h := (x_1^h, x_2^h)$ the homoclinic point that is closest to the unperturbed one $x^0(0)$.

The main goal of this paper is to give an asymptotic formula for the area $A$ of the lobe that remains between the two invariant curves from $x^h$ to their next intersection, as well as the angle $\alpha$ between the invariant curves at $x^h$. Our results are summarized in the next theorem.

**Theorem 1.1 (Main Theorem)** *Under hypotheses H1–H3, assume that $\gamma := p - \ell \geq 0$. Then, for $\varepsilon \to 0^+$, $\mu \to 0$, the following formulae hold:*

$$\begin{aligned} A &= \mu\varepsilon^p \left[\int_{s_0}^{\bar{s}_0} M(\sigma,\varepsilon)\,\mathrm{d}\sigma\right] + \mathrm{O}(\mu^2\varepsilon^{2\gamma+r}, \mu\varepsilon^{p+2})\,\mathrm{e}^{-a/\varepsilon}, \\ \sin\alpha &= \mu\varepsilon^p \frac{M'(s_0,\varepsilon)}{\|x^0(s_0)\|^2} + \mathrm{O}(\mu^2\varepsilon^{2\gamma+r-2}, \mu\varepsilon^p)\,\mathrm{e}^{-a/\varepsilon}, \end{aligned}$$

*where $s_0 < \bar{s}_0$ are the two zeros of the* Melnikov function

$$M(s,\varepsilon) = \int_{-\infty}^{+\infty} \{h^0, h^1\}(x^0(t+s), t/\varepsilon)\,\mathrm{d}t = \sum_{k\neq 0} M_k(\varepsilon)\,\mathrm{e}^{\mathrm{i}ks/\varepsilon}, \tag{1.4}$$

*closest to zero.*

This theorem gives upper estimates of exponentially small order for the area $A$ and the angle $\alpha$. Under a generic additional hypothesis on the Poisson bracket of $h^0$ and $h^1$ over $x^0(u)$:

*H4* $J_{\pm 1}(x^0(u))$ has a pole of order exactly $\ell + 1$ at $u = \pm a\mathrm{i}$, where

$$J(x,\theta) := \{h^0, h^1\}(x,\theta) = \sum_{k\neq 0} J_k(x)\,\mathrm{e}^{\mathrm{i}k\theta},$$

i.e., $J_{1,\ell+1} = \overline{J_{-1,\ell+1}} \neq 0$ in the Laurent expansion $J_{\pm 1}(x^0(u)) = \sum_{k\leq \ell+1} J_{\pm 1,k}(u \mp a\mathrm{i})^{-k}$ of $J_{\pm 1}(x^0(u))$ at $u = \pm a\mathrm{i}$, a direct computation of the Melnikov function shows that Theorem 1.1 provides asymptotic expressions:

**Corollary 1.2** *If moreover hypothesis H4 holds, the first terms of $A$ and $\sin\alpha$ in Theorem 1.1—those containing the Melnikov function (1.4)—are not zero and are dominant with respect to the second ones, for $\varepsilon \to 0^+$, $\mu \to 0$:*

$$\begin{aligned} A &= 4\,|J_{1,\ell+1}|\,\mu\varepsilon^{\gamma+1}\,\mathrm{e}^{-a/\varepsilon}\left[1+\mathrm{O}(\mu\varepsilon^{\gamma+r-1},\varepsilon^{\ell+1})\right], \\ \sin\alpha &= -\frac{2\,|J_{1,\ell+1}|}{\|x^0(0)\|^2}\mu\varepsilon^{\gamma-1}\,\mathrm{e}^{-a/\varepsilon}\left[1+\mathrm{O}(\mu\varepsilon^{\gamma+r-1},\varepsilon)\right]. \end{aligned}$$

Let us now show some examples verifying hypotheses *H1–H4*:

1. A *forced pendulum* equation, with Hamiltonian

$$h = \frac{x_2^2}{2} - (\cos x_1 + 1) + \mu\varepsilon^p x_2 \cos x_1 \sin\frac{t}{\varepsilon}\,. \tag{1.5}$$

   For $\mu = 0$, this system has homoclinic orbits $\Gamma_\pm = \{(x_1^0(t), \pm x_2^0(t))\}$, where $x_1^0(t) = 2\arctan(\sinh t)$, $x_2^0(u) = \dot{x}_1^0(u)$ has poles of order $r = 1$ at $u = \pm\pi\,\mathrm{i}/2$, and $\ell = 3$.

2. A perturbed *Duffing* equation, with Hamiltonian

$$h = \frac{x_2^2}{2} - \frac{x_1^2}{2} + \frac{x_1^4}{4} + \mu\varepsilon^p\left(\frac{x_2^2}{2}\cos\frac{t}{\varepsilon} + x_1 x_2 \sin\frac{2t}{\varepsilon}\right). \tag{1.6}$$

   For $\mu = 0$, the homoclinic orbits are $\Gamma_\pm = \{(\pm x_1^0(t), x_2^0(t))\}$, where $x_1^0(t) = \sqrt{2}/\cosh t$, $x_2^0(u) = \dot{x}_1^0(u)$ has poles of order $r = 2$ at $u = \pm\pi\,\mathrm{i}/2$, and $\ell = 4$.

3. A perturbed *cubic potential* equation, with Hamiltonian

$$h = \frac{x_2^2}{2} - \frac{x_1^2}{2} + \frac{x_1^3}{3} + \mu\varepsilon^p x_1 \cos\frac{t}{\varepsilon}\,. \tag{1.7}$$

   For $\mu = 0$, this system has the homoclinic orbit $\Gamma = \{(x_1^0(t), x_2^0(t))\}$, where $x_1^0(t) = (\sqrt{3}/2)\,(\cosh(t/2))^{-2}$, $x_2^0(u) = \dot{x}_1^0(u)$ has poles of order $r = 3$ at $u = \pm\pi\,\mathrm{i}$, and $\ell = 2$.

Applying Theorem 1.1 and Corollary 1.2 to the examples (1.5), (1.6) and (1.7), we get the following corollary.

**Corollary 1.3** *For $\varepsilon \to 0^+$, $\mu \to 0$, the following estimates hold:*

1. $A = \frac{16}{3}\pi\mu\varepsilon^{p-2}\,\mathrm{e}^{-\pi/2\varepsilon}[1+\mathrm{O}(\mu\varepsilon^{p-3},\varepsilon^4)]$, *for the pendulum equation (1.5), if $p \geq 3$;*
2. $A = \frac{4}{3}\pi\mu\varepsilon^{p-3}\,\mathrm{e}^{-\pi/2\varepsilon}[1+\mathrm{O}(\mu\varepsilon^{p-3},\varepsilon^5)]$, *for the Duffing equation (1.6), if $p \geq 4$;*
3. $A = 24\pi\mu\varepsilon^{p-1}\,\mathrm{e}^{-\pi/\varepsilon}[1+\mathrm{O}(\mu\varepsilon^p,\varepsilon^3)]$, *for the cubic potential equation (1.7), if $p \geq 2$.*

## Remarks on the hypotheses and the results

*R1* Hypothesis *H1* is clear: it requires a *separatrix* for the unperturbed solution to a saddle point, i.e., $f(0) = 0$, $f'(0) > 0$, and $\omega^0 := \sqrt{f'(0)} > 0$.

*R2* In hypothesis *H2*, the analyticity of $x_2^0(u)$ on a complex strip $|\Im u| < a$ is assumed. This is not a restriction for an analytic unperturbed system, since the separatrix behaves regularly for $\Re t \to \pm\infty$. The actual restriction is the assumption that the *only* singularity of $x_2^0(u)$ on each component of the boundary of this strip is a *pole* of some order $r \geq 1$, which implies a severe restriction on the behaviour of $f(x_1)$ for $x_1$ big enough. More precisely, if $r \geq 2$, the equation $f(x_1(u)) = \ddot{x}_1(u)$ on an entire function $f$ forces $f(x_1)$ to be a polynomial of degree 2 or 3, for $r = 3$ or $r = 2$, respectively. Analogously, $r = 1$ can only take place if $f(x_1)$ is a trigonometric polynomial of degree 1 or 2, and then $x_1^0(u) \sim \mathrm{i}k\log(u \mp a\mathrm{i})$ $(u \to \pm a\mathrm{i})$, with $k$ equal to 2 or 1, respectively. Another values of $r$ and of the degree of the (trigonometric) polynomial $f(x_1)$ give rise to branching points ("poles of fractional order") as singularities of $x_2^0(u)$.

Actually, our method also applies to $x_2^0$ with branching points (and even to meromorphic $f$ and $h^1$), but in this paper we only consider a meromorphic $x_2^0$ for simplicity and to be able to compute explicitly the Melnikov function. However, it is worth mentioning that in the case of an essential singularity for $x_2^0$, it seems difficult to control the behaviour of the perturbed invariant manifolds, and even it is not clear at all which kind of asymptotics for splitting of separatrices could take place (see [SMH91] for a related discussion).

*R3* Along all this paper, the parameter $\ell$ provided by hypothesis *H3* will be called the *order of the perturbation on the separatrix* or, even more precisely, the order of the perturbation on the singularity of the homoclinic solution. It is worth noting that Theorem 1.1 holds under the assumption $p :=$ power of $\varepsilon \geq \ell =$ order of the perturbation on the separatrix.

By its definition, $\ell$ satisfies $\ell \geq r - 1$. In general, $\ell$ will be the order of the pole of $h^1(x^0(u), \theta)$ at $u = \pm a\mathrm{i}$, if there is no cancellation between the different monomies of $h^1$, when evaluated on $x^0(u)$. An example where these cancellations take place is provided by $h^1 = h^0(x)$, as $h^0(x^0(u))$ is constant (and hence with no pole at all), but for instance its monomy $x_2^2/2$ has a pole of order $2r$. The same happens if $h^1$ is functionally dependent on $h^0$.

Let us note that in the case $h^1(x, \theta) = x_1 g(\theta)$, system (1.2) is equivalent to the scalar equation $\ddot{x}_1 = f(x_1) + \mu\varepsilon^p g(t/\varepsilon)$, i.e., the perturbation only depends on time. In the trigonometric case, $x_1^0(u)$ has logarithmic singularities, but the results of Theorem 1.1 are still valid if we take, by convention, $\ell = 0$.

*R4* As a matter of fact, hypothesis *H3* is more restrictive than necessary. The needed hypothesis for our method is a little bit more technical and is given in Lemmas 4.2

and 5.1, which simply establish the size of the perturbation $h^1(x,\theta)$ and its derivatives for $x$ near $x^0(u)$ and $u$ close to $a\mathrm{i}$ in terms of the order $\ell$.

Namely, the only important fact is to control the derivatives of $h^1$ over the separatrix $x^0(u)$ near the singularity $u = a\mathrm{i}$. For instance, if $h^1$ has only a monomy and $h^1(x^0(u),\theta)$ has a pole of order $\ell$, then its derivative with respect to $u$

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}u}h^1(x^0(u),\theta) &= \{h^0,h^1\}(x^0(u),\theta)\\ &= \partial_1 h^1(x^0(u),\theta)x_2^0(u) + \partial_2 h^1(x^0(u),\theta)\dot{x}_2^0(u) \qquad (1.8)\end{aligned}$$

has a pole of order $\ell+1$, and hence $\partial_1 h^1(x^0(u),\theta)$ has a pole of order $\ell+1-r$ and $\partial_2 h^1(x^0(u),\theta)$ has a pole of order $\ell - r$. The same happens if $h^1$ verifies hypothesis *H3* and $\ell$ is the order of the perturbation on the singularity of the homoclinic solution, i.e., $\ell$ is taken as the greatest order of the different monomies of $h^1$.

*R5* We note that if $h^1(x^0(u),\theta)$ has a pole of order $\ell' \le \ell$, then its derivative with respect to $u$ (1.8) has a pole of order $\ell'+1$. Hypothesis *H4* requires that this pole is realized in the first harmonic with respect the parameter $\theta$, and that $\ell' = \ell$, i.e., that there are no cancellations between the different monomies of $h^1$, when evaluated on $x^0(u)$. It is clear that hypothesis *H4* is a generic condition. The case $\ell' < \ell$ would require a larger $p$ in order to prove Theorem 1.1.

*R6* Our measure of the splitting of the separatrices is given by the so-called *splitting function* $\psi(S)$, defined in (2.24) as the graphic of the unstable manifold over the stable one, in some suitable "flow-box" canonical coordinates. This is a $2\pi\varepsilon$-periodic function, whose zeros give rise to homoclinic orbits, and all the splitting quantities are obtained from it. Thus, the area $A$ and the angle $\alpha$ given in Theorem 1.1 are expressed in terms of the integral and the derivative of the splitting function $\psi$. Another related quantities that measure the splitting of separatrices could also be computed, like the maximum distance $d$ between the invariant curves at the lobe and the Lazutkin homoclinic invariant [GLT91] which is simply $\psi'(h^{\mathrm{s}})$ in the notation of Proposition 2.7.

*R7* Two remarkable recent works related with this paper are [Gel95] and [Gal94].

V. Gelfreich [Gel95] considers a Hamiltonian of the form

$$H = H_0(x,y) + \mu H_1(x,y,t/\varepsilon;\varepsilon,\mu)$$

and establishes sufficient conditions for the validity of the Melnikov method provided $|\mu| < \mu_0\varepsilon^p$ for some constant $p$. His method resembles ours, but the constant $p$ is related to the validity of an extension theorem like our Theorem 2.4, which is not carried out and because of this, $p$ is not given in explicit examples.

G. Gallavotti [Gal94] considers the rotator-pendulum model (also called the resonance model) given by a Hamiltonian

$$\frac{\omega_0 A}{\varepsilon} + \frac{A^2}{2J} + \frac{I^2}{2J_0} + g^2 J_0(\cos\varphi - 1) + \mu \sum_{\substack{|n|+|\nu|\le N \\ \nu\neq 0}} f_{n,\nu}\cos(\alpha\nu + n\varphi),$$

where $(\varphi, I) \in \mathbf{R}^2$ and $(\alpha, A)$ are canonically conjugated variables and $\omega_0$, $J_0$, $J$, $g$ are positive parameters with $J_0 \le J \le \infty$. Under the assumption $|\mu| \le \varepsilon^{2q}$, $q > 3N_0 + 5$, where $N_0$ is the degree in $\varphi$ of the trigonometrical polynomial above, he proves that the splitting distance is given by the Melnikov function. His proof is based on an algorithm derived in [CG94] for the computation of the $\mu$-expansion coefficients of the invariant manifolds and the exponential smallness is obtained explicitly checking cancellation mechanisms, operating to all orders.

We emphasize that his method can be applied to a broader setting, i.e., $n$-degrees of freedom Hamiltonians, and that his condition above on $q$ for $n = 2$ reads as $p > 6N_0 + 10 = 3\ell + 10$ in our notation (or $p > \ell + 9$, following some ideas given in the appendix of [Gal94]), whereas we only require $p \ge \ell$.

*R8* Concerning optimality of $p$, our estimates are valid for $p \ge \ell$, which is the condition required for the Extension Theorem 2.4 in the complex strip (2.16). We believe that this Extension Theorem is not true if $p < \ell$ (this has to do with the fact that the term $\mu\varepsilon^p M(s,\varepsilon)$ of the Melnikov method is not small in the complex strip $|\Im s| \le a - \varepsilon$ for $p < \ell$). Of course, we do not claim that $p \ge \ell$ is the optimal lower bound, but it is clear that other methods are needed for lower ranges of $p$. For instance, D. Treschev [Tre94], using a continuous averaging method, proves for an specific trigonometrical example with $\ell = 2$, that the splitting is given by the Melnikov method for $p > 0 = \ell - 2$. Also in the trigonometric case, G. Gallavotti [Gal94] gives $p > \ell - 1$ as a probably optimal lower bound, and recent papers by C. Simó [Sim94] and V. Gelfreich [Gel94], seem to indicate that the lower bound can be $p > \ell - 2$.

*R9* The structure of this paper is devoted to give full and comprehensible details of the proof of the Main Theorem 1.1, and more concretely, of the construction of the splitting function. In section 2, all the main ideas are introduced, as well as the main tools: first, the Normal Form Theorem and its Corollaries, which provide good (complex) parameterizations for the local invariant manifolds associated to the periodic orbit of system (1.2), as well as Flow Box Coordinates near the local stable manifold; second, the Extension Theorem, which justifies the prolongation of the unstable manifold until it passes again near the periodic orbit; and third, Propositions 2.6 and 2.7, which allow us to define the splitting function $\psi$, to relate it to the Melnikov function and give, as a direct consequence, the proof of the Main Theorem. To avoid a premature incursion into technicalities, the proofs of these tools, as well as Corollary 1.2, are deferred to successive sections.

# 2 Proof of the Main Theorem

From now on, hypotheses *H1–H3* and the condition $\gamma = p - \ell \geq 0$ will be implicitly assumed, and $\varepsilon > 0$ and $\mu$ will denote small enough independent parameters. To avoid a cumbersome notation, the dependence of all the functions on $\mu$, $\varepsilon$ is not explicitly written, but is always assumed continuous and bounded.

First of all, next theorem deals with the local behaviour of system (1.2) and states that the Birkhoff normal form is convergent in a neighbourhood of the origin.

**Theorem 2.1 (Normal Form Theorem)** *System (1.2) verifies the following properties:*

1. *There exists a $2\pi\varepsilon$-periodic orbit near the origin $\gamma_p(t/\varepsilon)$, with*

$$\gamma_p(\theta) = (\gamma_1(\theta), \gamma_2(\theta)) = \mu\varepsilon^{p+1} G(0,\theta) + \mathrm{O}(\mu\varepsilon^{p+2}),$$

*where $G = (G_1, G_2)$ is related to $h^1$ through*

$$\partial_\theta G(x,\theta) = \left(\partial_2 h^1(x,\theta), -\partial_1 h^1(x,\theta)\right), \qquad \int_0^{2\pi} G(x,\theta)\,\mathrm{d}\theta = 0. \tag{2.1}$$

2. *There exists a canonical change of variables*

$$(X, \theta = t/\varepsilon) \longmapsto (x = \Psi(X,\theta), \theta) \tag{2.2}$$

*with*

$$\Psi(X,\theta) = \Psi(X,\theta,\mu,\varepsilon) = \Psi^0(X) + \mu\varepsilon^{p+1} G(\Psi^0(X),\theta) + \mathrm{O}(\mu\varepsilon^{p+2}), \tag{2.3}$$

*analytic in $X$ and $2\pi$-periodic and $\mathcal{C}^2$ in $\theta$ for $|X_1|^2 + |X_2|^2 < R_0^2$, $\theta \in \mathbf{R}$, with $R_0$ independent of $\varepsilon$, $\mu$, such that transforms system (1.2) into its normal form:*

$$\dot{X}_1 = F'(X_1X_2,\mu,\varepsilon)X_1, \qquad \dot{X}_2 = -F'(X_1X_2,\mu,\varepsilon)X_2. \tag{2.4}$$

*This system is a Hamiltonian system with associated Hamiltonian*

$$H(X,\theta,\mu,\varepsilon) := F(X_1X_2,\mu,\varepsilon) = F^0(X_1X_2) + \mu\varepsilon^{p+2} F^1(X_1X_2,\mu,\varepsilon), \tag{2.5}$$

*with*

$$F(I,\mu,\varepsilon) = \omega I + \mathrm{O}(I^2), \quad F'(I,\mu,\varepsilon) = \omega + \mathrm{O}(I), \quad \omega = \omega^0 + \mathrm{O}(\mu\varepsilon^{p+2}), \tag{2.6}$$

*where $F'(I,\mu,\varepsilon)$ denotes the derivative of $F$ with respect to its first variable $I$.*

3. *The change of variables $x = \Psi^0(X)$ transforms system (1.1) into its normal form, which is the Hamiltonian system associated to $F^0(X_1X_2) = \omega^0 X_1X_2 + \mathrm{O}(X_1^2X_2^2)$.*

From a quantitative point of view, Theorem 2.1 states that: (i) the region of convergence of the normal form is independent of $\varepsilon$, $\mu$; (ii) the periodic orbit $\gamma_p$ and the change of variables $\Psi$ are $\mathrm{O}(\mu\varepsilon^{p+1})$-close to the unperturbed ones: 0 and $\Psi^0$, respectively; and (iii) the normal form $F$ and the characteristic exponent $\omega$ are $\mathrm{O}(\mu\varepsilon^{p+2})$-close to $F^0$ and $\omega^0$, respectively (this extra $\varepsilon$ is due to the zero mean of $h^1$). Its proof is based on a quantitative version of a well known theorem due to Moser [Mos56], and is deferred to section 3. Another more recent proofs, valid for more degrees of freedom, can be found in [CG94,DGJS96,RW95].

Since system (2.4) can be explicitly solved, Theorem 2.1 supplies us with the basic tools to control the local behaviour of the orbits. In particular, good parameterizations $x^{\mathrm{u}}(t,s)$ and $x^{\mathrm{s}}(t,s)$ for the local invariant manifolds, $W^{\mathrm{u}}_{\mathrm{loc}}(\gamma_p)$ and $W^{\mathrm{s}}_{\mathrm{loc}}(\gamma_p)$, are easily found and their properties are summarized in the next corollary.

**Corollary 2.2 (Local Invariant Manifolds)** *There exist parameterizations $x^{\mathrm{u}}(t,s)$, $x^{\mathrm{s}}(t,s)$ of the unstable and stable invariant local manifolds of system (1.2), defined in $D^{\mathrm{u}}$, $D^{\mathrm{s}}$, respectively, with:*

$$D^{\mathrm{u}} := \{(t,s) \in \mathbf{R}\times\mathbf{C} : t + \Re s \le -T/2\}, \tag{2.7}$$
$$D^{\mathrm{s}} := \{(t,s) \in \mathbf{R}\times\mathbf{C} : t + \Re s \ge T/2\}, \tag{2.8}$$

*with $T$ some constant independent of $\mu$, $\varepsilon$, which satisfy the following properties ($*$ stands for* s *and* u*):*

1. *$t \mapsto x^*(t,s)$ is a solution of system (1.2) and $s \mapsto x^*(t,s)$ is real analytic.*

2. *$x^*(t+2\pi\varepsilon, s) = x^*(t, s+2\pi\varepsilon)$, and thus the local stable and local unstable curves for the Poincaré map (1.3) are given by $C^*_{\mathrm{loc}} = \{x^*(2\pi n\varepsilon, s)\}$, for any $n \in \mathbf{N}$ such that $(2\pi n\varepsilon, s) \in D^*$.*

3. *For $\mu = 0$, $x^*(t,s)$ coincides with the homoclinic solution $x^0(t+s)$, and for $\mu \neq 0$ the following estimate holds:*

$$x^*(t,s) = x^0(t+s) + \mu\varepsilon^{p+1} G(x^0(t+s), t/\varepsilon) + \mathrm{O}(\mu\varepsilon^{p+2}). \tag{2.9}$$

4. *Near the periodic orbit $\gamma_p$, the following asymptotics are satisfied:*

$$\begin{aligned} x^{\mathrm{u}}(t,s) &= \gamma_p(t/\varepsilon) + x^0(t+s) + \mathrm{O}(\mu\varepsilon^{p+1}\,\mathrm{e}^{\omega(t+s)}) + \mathrm{O}(\mu\varepsilon^{p+2}\,\mathrm{e}^{(t+s)/2}),\\ x^{\mathrm{s}}(t,s) &= \gamma_p(t/\varepsilon) + x^0(t+s) + \mathrm{O}(\mu\varepsilon^{p+1}\,\mathrm{e}^{-\omega(t+s)}) + \mathrm{O}(\mu\varepsilon^{p+2}\,\mathrm{e}^{-(t+s)/2}), \end{aligned} \tag{2.10}$$

   *$\omega$ being the positive constant defined in formula (2.6) as the characteristic exponent of the periodic orbit $\gamma_p$.*

The parameterizations $x^{\mathrm{u}}(t,s)$, $x^{\mathrm{s}}(t,s)$, can be considered as "natural" [DR96]: they are formed by solutions of system (1.2) in the real variable $t$, and the action of the Poincaré map is simply a shift of amount $2\pi\varepsilon$ in the complex variable $s$. It is

worth mentioning that they are not uniquely determined, since a new parameterization $\tilde{x}^*(t,S) = x^*(t, S+\phi(S))$ (i.e., a change of parameter $s = S + \phi(S)$), for a $2\pi\varepsilon$-periodic function $\phi$ of size $\mathrm{O}(\mu\varepsilon^{p+1})$, does not change the properties above, but only may restrict the domain of analyticity of $S \mapsto \tilde{x}^*(t,S)$. We will use this indefiniteness later on.

Another consequence of the explicit resolution of system (2.4), is that performing there the change of variables $S = -\log X_2/F'(X_1X_2)$, $E = F(X_1X_2)$, and composing it with the change of variables (2.2) to normal form, one obtains the existence of local flow box coordinates outside of the local unstable invariant manifold $W^{\mathrm{u}}_{\mathrm{loc}}(\gamma_p)$.

**Corollary 2.3 (Flow Box Theorem)** *There exists a canonical change of variables*

$$(x, \theta = t/\varepsilon) \in \mathcal{U} \longmapsto (S, E, \theta) = (\mathcal{S}(x,\theta), \mathcal{E}(x,\theta), \theta) \in \mathcal{V}, \tag{2.11}$$

*analytic in $x$, $2\pi$-periodic and $\mathcal{C}^2$ in $\theta$ on $\mathcal{U} = \{(x,\theta) \in \mathbf{C}^2 \times \mathbf{R} : \|x - \gamma_p(\theta)\| < r_0^2\} \setminus W^{\mathrm{u}}_{\mathrm{loc}}(\gamma_p)$, with $r_0$ independent of $\mu$, $\varepsilon$, such that transforms system (1.2) in a flow box system*

$$\dot{S} = 1, \qquad \dot{E} = 0, \tag{2.12}$$

*and verifies:*

1. $$\mathcal{S}(x,\theta) = \mathcal{S}^0(x) + \mathrm{O}(\mu\varepsilon^{p+1}), \qquad \mathcal{E}(x,\theta) = \mathcal{E}^0(x) + \mathrm{O}(\mu\varepsilon^{p+1}), \tag{2.13}$$
   *where $x \mapsto (\mathcal{S}^0(x), \mathcal{E}^0(x) = h^0(x))$ is the corresponding change for system (1.1).*

2. *Denoting $(S,E,\theta) \in \mathcal{V} \longmapsto (\mathcal{X}(S,E,\theta),\theta) \in \mathcal{U}$ the inverse change to (2.11), the following estimate holds*
   $$\mathcal{X}(S,E,\theta) = \mathcal{X}^0(S,E) + \mathrm{O}(\mu\varepsilon^{p+1}), \tag{2.14}$$
   *where $x = \mathcal{X}^0(S,E)$ is the inverse change to $x \mapsto (S,E) = (\mathcal{S}^0(x), \mathcal{E}^0(x))$.*

3. *Along the local stable manifold $x^{\mathrm{s}}(t,s)$, the flow-box functions (2.11) satisfy*
   $$\mathcal{S}(x^{\mathrm{s}}(t,s), t/\varepsilon) = t + s, \qquad \mathcal{E}(x^{\mathrm{s}}(t,s), t/\varepsilon) = 0. \tag{2.15}$$

Up to now, the parameterization $x^{\mathrm{u}}(t,s)$ of the unstable manifold has been only defined for $(t,s) \in D^{\mathrm{u}}$ given by (2.7). To extend it for other values of $(t,s)$, we would like to use an analog of estimate (2.9), which relates $x^{\mathrm{u}}(t,s)$ to the unperturbed separatrix $x^0(t+s)$. However, $x^0(u)$ has a singularity in the complex field at $u = \pm a\mathrm{i}$; more precisely, since $x_2^0(u) = \dot{x}_1^0(u)$ has a pole of order $r$ at these points, it behaves like

$$x_2^0(u) = \frac{\mp \mathrm{C}\,\mathrm{i}}{(u \mp a\mathrm{i})^r}\left(1 + \mathrm{O}(u \mp a\mathrm{i})\right),$$

with C a non-zero constant, for $u$ near $\pm a\mathrm{i}$. This means that we will not be able to control the growth of the parameterization for $t + s = \pm a\mathrm{i}$, i.e., for $\Im s = \pm a$, since

the time $t$ is always assumed to be real. We will restrict ourselves, like in [DS92], to a complex strip $\mathcal{D}^{\mathrm{u}}_{\varepsilon}$ of imaginary width equal to $a-\varepsilon$:

$$\mathcal{D}^{\mathrm{u}}_{\varepsilon} := \{(t,s) \in \mathbf{R} \times \mathbf{C} : \quad |\Im s| \leq a-\varepsilon, \quad |t+\Re s| \leq T\}. \tag{2.16}$$

The following Extension Theorem ensures us that the parameterization $x^{\mathrm{u}}(t,s)$ of the unstable invariant manifold $W^{\mathrm{u}}(\gamma_p)$ is still defined and close enough to the unperturbed separatrix. We state it first, for the sake of generality, for arbitrary solutions $x(t,s)$ of (1.2).

**Theorem 2.4 (Extension Theorem)** *Let $x^0(t+s)$ be the unperturbed separatrix of system (1.1), and $x(t,s)$ a family of solutions of (1.2) such that*

$$x(t_0,s) - x^0(t_0+s) - \mu\varepsilon^{p+1} G(x^0(t_0+s), t_0/\varepsilon) = \mathrm{O}(\mu\varepsilon^{p+2}), \tag{2.17}$$

*where $s \in \mathbf{C}$, $|\Im s| \leq a-\varepsilon$, and $t_0 + \Re s = -T$.*

*Then, if $\gamma = p - \ell \geq 0$, $x(t,s)$ is defined on $\mathcal{D}^{\mathrm{u}}_{\varepsilon}$ given in (2.16) and satisfies there:*

$$x(t,s) - x^0(t+s) = \mathrm{O}(\mu\varepsilon^{\gamma}).$$

The proof of this theorem involves several technicalities, as a good choice of the solutions of the variational equations associated to the separatrix and the partition of the strip $\mathcal{D}^{\mathrm{u}}_{\varepsilon}$ in different regions. Apart from this, it relies on straightforward estimates, following the same arguments as those in [DS92,DGJS96,RW96], and is deferred to section 4.

By estimate (2.9), it is clear that the parameterization $x^{\mathrm{u}}(t,s)$ of $W^{\mathrm{u}}_{\mathrm{loc}}(\gamma_p)$ satisfies the hypotheses of the Extension Theorem for $t_0 = -\Re s - T$, and consequently the following estimate holds

$$x^{\mathrm{u}}(t,s) - x^0(t+s) = \mathrm{O}(\mu\varepsilon^{\gamma}), \quad (t,s) \in \mathcal{D}^{\mathrm{u}}_{\varepsilon}. \tag{2.18}$$

**Remark 2.5** It has to be noticed here that for fixed $T$ and $s \in \mathbf{R}$, this Extension Theorem becomes a well-known result and estimate (2.18) is of the same order as the one at initial condition (2.17), i.e.,

$$x^{\mathrm{u}}(t,s) - x^0(t+s) = \mu\varepsilon^{p+1} G(x^0(t+s), t/\varepsilon) + \mathrm{O}(\mu\varepsilon^{p+2}), \tag{2.19}$$

for $-T \leq t+s \leq T$, and $t, s \in \mathbf{R}$.

By hypothesis *H1*, and more precisely by estimate (2.10), $x^0(t+s)$ arrives and stays at the open set $\mathcal{U}$ for $t+\Re s \geq T/2$. By estimate (2.18), the same happens to $x^{\mathrm{u}}(t,s)$ for $T/2 \leq t+\Re s \leq T$, and $|\Im s| \leq a-\varepsilon$. On $\mathcal{U}$, the flow-box functions (2.11) are defined, and therefore can be evaluated on the unstable manifold giving rise to two functions:

$$\mathcal{S}^{\mathrm{u}}(s) := \mathcal{S}(x^{\mathrm{u}}(t,s), t/\varepsilon) - t, \qquad \mathcal{E}^{\mathrm{u}}(s) := \mathcal{E}(x^{\mathrm{u}}(t,s), t/\varepsilon), \tag{2.20}$$

defined for $|\Im s| \leq a - \varepsilon$. In equation (2.20), the time $t$ on the right terms has been chosen in $T/2 \leq t + \Re s \leq T$, but $\mathcal{S}^{\mathrm{u}}$ and $\mathcal{E}^{\mathrm{u}}$ do not depend on $t$ since, by Corollary 2.3, $\mathcal{S}(x, t/\varepsilon) - t$ and $\mathcal{E}(x, t/\varepsilon)$ are real analytic first integrals of system (1.2). Besides, by properties (1) and (2) of Corollary 2.2, it turns out that $\mathcal{S}^{\mathrm{u}}(s) - s$ and $\mathcal{E}^{\mathrm{u}}(s)$ are analytic for $|\Im s| \leq a - \varepsilon$ and $2\pi\varepsilon$-periodic in $s$.

The next Proposition asserts that $\mathcal{E}^{\mathrm{u}}(s)$ is given in first order by the Melnikov function, for $|\Im s| \leq a - \varepsilon$, and as a consequence, that the difference between $\mathcal{E}^{\mathrm{u}}(s) - \mathcal{E}_0^{\mathrm{u}}$ and $\mu\varepsilon^p M(s, \varepsilon)$ is $\mathrm{O}(\mathrm{e}^{-a/\varepsilon})$ for real $s$, where $\mathcal{E}_0^{\mathrm{u}}$ is the zero order Fourier coefficient of $\mathcal{E}^{\mathrm{u}}$.

**Proposition 2.6** *For $\gamma = p - \ell \geq 0$, $\mathcal{S}^{\mathrm{u}}$ and $\mathcal{E}^{\mathrm{u}}$ verify the following estimates:*

1. *For $s \in \mathbf{C}$ such that $|\Im s| \leq a - \varepsilon$,*

$$\mathcal{E}^{\mathrm{u}}(s) = \mu\varepsilon^p M(s, \varepsilon) + \mathrm{O}(\mu^2\varepsilon^{2\gamma+r-1}, \mu\varepsilon^{p+1}). \tag{2.21}$$

2. *For $s \in \mathbf{R}$, and $\mathcal{E}_0^{\mathrm{u}} = \frac{1}{2\pi\varepsilon}\int_0^{2\pi\varepsilon} \mathcal{E}^{\mathrm{u}}(s)\,\mathrm{d}s$,*

$$\mathcal{E}^{\mathrm{u}}(s) - \mathcal{E}_0^{\mathrm{u}} = \mu\varepsilon^p M(s, \varepsilon) + \mathrm{O}(\mu^2\varepsilon^{2\gamma+r-1}, \mu\varepsilon^{p+1})\,\mathrm{e}^{-a/\varepsilon}. \tag{2.22}$$

3. *For $s \in \mathbf{R}$, $S = \mathcal{S}^{\mathrm{u}}(s)$ is real analytic and invertible, and its inverse $s = s^{\mathrm{u}}(S)$ verifies that $s^{\mathrm{u}}(S) - S$ is $\mathrm{O}(\mu\varepsilon^{p+1})$ and $2\pi\varepsilon$-periodic in $S$.*

From Corollary 2.3, and in particular from equations (2.15), it turns out that the local stable manifold $x^{\mathrm{s}}(t, s)$ has a very simple expression in the $(S, E)$ coordinates:

$$(S, E) = (\mathcal{S}(x^{\mathrm{s}}(t, s), t/\varepsilon), \mathcal{E}(x^{\mathrm{s}}(t, s), t/\varepsilon)) = (t + s, 0),$$

i.e., $E = 0$. Using equations (2.20), the arriving unstable manifold $x^{\mathrm{u}}(t, s)$ has in these coordinates the expression

$$(S, E) = (\mathcal{S}(x^{\mathrm{u}}(t, s), t/\varepsilon), \mathcal{E}(x^{\mathrm{u}}(t, s), t/\varepsilon)) = (t + \mathcal{S}^{\mathrm{u}}(s), \mathcal{E}^{\mathrm{u}}(s))$$

and, in particular, the unstable curve $C^{\mathrm{u}}$ of the Poincaré map $P$ defined in (1.3), is given by $(S, E) = (2\pi n\varepsilon + \mathcal{S}^{\mathrm{u}}(s), \mathcal{E}^{\mathrm{u}}(s))$, using property (2) of Corollary 2.2.

Therefore, it is very natural to introduce the *splitting function* $\psi$ given implicitly by $\psi(2\pi n\varepsilon + \mathcal{S}^{\mathrm{u}}(s)) = \mathcal{E}^{\mathrm{u}}(s)$, or simply by $\psi(\mathcal{S}^{\mathrm{u}}(s)) = \mathcal{E}^{\mathrm{u}}(s)$, using that $\mathcal{S}^{\mathrm{u}}(s) - s$ and $\mathcal{E}^{\mathrm{u}}(s)$ are $2\pi\varepsilon$-periodic in $s$. By Proposition 2.6, $S = \mathcal{S}^{\mathrm{u}}(s)$ can be inverted for real values of $s$, giving rise to the inverse function $s = s^{\mathrm{u}}(S)$. Consequently, $\psi(S)$ is explicitly defined, for real values of $S$, as

$$\psi(S) = \mathcal{E}^{\mathrm{u}}(s^{\mathrm{u}}(S)). \tag{2.23}$$

Since $s^{\mathrm{u}}(S) - S$ is $\mathrm{O}(\mu\varepsilon^{p+1})$ and $2\pi\varepsilon$-periodic in $s$, we can introduce a new natural parameterization for the unstable invariant manifold (see the comments following Corollary 2.2)

$$\tilde{x}^{\mathrm{u}}(t, S) = x^{\mathrm{u}}(t, s^{\mathrm{u}}(S)),$$

and by (2.15) we can simply write for the stable invariant manifold

$$\tilde{x}^{\mathrm{s}}(t,S) = x^{\mathrm{s}}(t,S),$$

in such a way that $\psi(S)$ can be also written as

$$\begin{aligned}\psi(S) &= \mathcal{E}(x^{\mathrm{u}}(t,s^{\mathrm{u}}(S)),t/\varepsilon)\\ &= \mathcal{E}(x^{\mathrm{u}}(t,s^{\mathrm{u}}(S)),t/\varepsilon) - \mathcal{E}(x^{\mathrm{s}}(t,S),t/\varepsilon)\\ &= \mathcal{E}(\tilde{x}^{\mathrm{u}}(t,S),t/\varepsilon) - \mathcal{E}(\tilde{x}^{\mathrm{s}}(t,S),t/\varepsilon)\\ &= \mathcal{E}(\tilde{x}^{\mathrm{u}}(t,S),t/\varepsilon). \qquad (2.24)\end{aligned}$$

It only remains to confirm that $\psi$ measures the splitting, and this is done in the next Proposition.

**Proposition 2.7** *The function $\psi$ is a $2\pi\varepsilon$-periodic, real analytic function that satisfies the following properties.*

1. *There exist $h^{\mathrm{u}} \in \mathbf{R}$ such that $x^{\mathrm{u}}(t,h^{\mathrm{u}}) = x^{\mathrm{s}}(t,h^{\mathrm{s}})$ (giving an homoclinic connection), with $h^{\mathrm{s}} = \mathcal{S}^{\mathrm{u}}(h^{\mathrm{u}})$. Consequently, $\psi(h_n) = 0$, for $h_n = h^{\mathrm{s}} + 2\pi\varepsilon n$, $n \in \mathbf{N}$. Moreover, $\psi'(h_n)$ is independent of $n$, and*

$$\psi'(h_n) = \frac{\partial x^{\mathrm{s}}}{\partial S}(t,h_n) \wedge \frac{\partial \tilde{x}^{\mathrm{u}}}{\partial S}(t,h_n) = \left\|\frac{\partial x^{\mathrm{s}}}{\partial S}(t,h_n)\right\| \cdot \left\|\frac{\partial \tilde{x}^{\mathrm{u}}}{\partial S}(t,h_n)\right\| \sin\alpha(t,h_n),$$

   *where $\wedge$ denotes the exterior product on $\mathbf{R}^2$, and $\alpha(t,h_n)$ is the angle between $x^{\mathrm{u}}(t,h^{\mathrm{u}}+2\pi\varepsilon n) = \tilde{x}^{\mathrm{u}}(t,h_n)$ and $x^{\mathrm{s}}(t,h_n)$.*

2. *$A = \left|\int_{h_n}^{\bar{h}_n} \psi(S)\,\mathrm{d}S\right|$, where $h_n$ and $\bar{h}_n$ are the two consecutive zeros of $\psi(S)$ closest to zero.*

3. *$\psi_0 = \int_{h_n}^{h_n+2\pi\varepsilon} \psi(S)\,\mathrm{d}S = 0$.*

4. *$\psi(S)$ verifies for $S \in \mathbf{R}$ the estimate*

$$\psi(S) = \mu\varepsilon^p M(S,\varepsilon) + \mathrm{O}(\mu^2\varepsilon^{2\gamma+r-1}, \mu\varepsilon^{p+1})\,\mathrm{e}^{-a/\varepsilon}. \qquad (2.25)$$

Now all the statements of Theorem 1.1 follow from Proposition (2.7) and specially from the approximations given in (2.25).

# 3 Proof of the Normal Form Theorem and its Corollaries

## Proof of Theorem 2.1

First of all, it is better to make the change of time $\theta = t/\varepsilon$ to system (1.2), obtaining

$$\begin{aligned}x_1' &= \varepsilon x_2 + \mu\varepsilon^{p+1}\partial_2 h^1(x,\theta),\\ x_2' &= \varepsilon f(x_1) - \mu\varepsilon^{p+1}\partial_1 h^1(x,\theta),\end{aligned} \qquad (3.1)$$

which is a Hamiltonian system with Hamiltonian

$$\varepsilon h(x,\theta,\mu,\varepsilon) = \varepsilon h^0(x) + \mu\varepsilon^{p+1} h^1(x,\theta).$$

System (3.1) will be put into its normal form with the aid of several lemmas. As a first step, we deal with its averaged system.

**Lemma 3.1** *There exists a canonical change*

$$\bar{x} \longmapsto x = \Pi(\bar{x},\theta,\mu,\varepsilon) = \bar{x} + \mu\varepsilon^{p+1} G(\bar{x},\theta) + \mathrm{O}(\mu\varepsilon^{p+2}), \tag{3.2}$$

*$2\pi$-periodic and $\mathcal{C}^2$ in $\theta$, and analytic in $\bar{x}$, with $G$ defined in (2.1), such that transforms system (3.1) into a Hamiltonian system of Hamiltonian $\varepsilon\mathcal{H}$, where*

$$\mathcal{H}(\bar{x},\theta,\mu,\varepsilon) = h^0(\bar{x}) + \mu\varepsilon^{p+2}\mathcal{R}(\bar{x},\theta,\mu,\varepsilon), \tag{3.3}$$

*$\mathcal{R}$ being analytic with respect to $\bar{x}$, and $2\pi$-periodic and $\mathcal{C}^1$ in $\theta$.*

*Proof.* We only have to check that the generating function

$$S(x_1,\bar{x}_2,\theta,\mu,\varepsilon) = x_1\bar{x}_2 + \mu\varepsilon^{p+1} S^1(x_1,\bar{x}_2,\theta) + \mu\varepsilon^{p+2} S^2(x_1,\bar{x}_2,\theta)$$

defined by:

$$\begin{aligned} \partial_\theta S^1(x_1,\bar{x}_2,\theta) &= -h^1(x_1,\bar{x}_2,\theta), \quad \int_0^{2\pi} S^1(x_1,\bar{x}_2,\theta)\,\mathrm{d}\theta = 0, \\ \partial_\theta S^2(x_1,\bar{x}_2,\theta) &= V'(x_1)\partial_2 S^1(x_1,\bar{x}_2,\theta) - \bar{x}_2\partial_1 S^1(x_1,\bar{x}_2,\theta), \end{aligned}$$

provides implicitly, through $\bar{x}_1 = \partial_2 S(x_1,\bar{x}_2,\theta,\mu,\varepsilon)$, $x_2 = \partial_1 S(x_1,\bar{x}_2,\theta,\mu,\varepsilon)$, a canonical change $\Pi$ satisfying (3.2) and (3.3). $\partial_2$ denotes $\partial/\partial\bar{x}_2$ along this proof.

We first note that by hypothesis *H3*, $h^1$ has zero mean and consequently the equations above for the $2\pi$-periodic in $\theta$ functions $S^1$, $S^2$ can be solved, giving rise to a canonical change $\Pi$ of the form (3.2). Under this change, the new Hamiltonian $\varepsilon\mathcal{H}$ verifies

$$\varepsilon\mathcal{H}(\partial_2 S,\bar{x}_2,\theta,\mu,\varepsilon) = \varepsilon h(x_1,\partial_1 S,\theta,\mu,\varepsilon) + \partial_\theta S,$$

for $S = S(x_1,\bar{x}_2,\theta,\mu,\varepsilon)$, and the right side of this equality can be expanded, using the definitions of $S^1$, $S^2$, to

$$\begin{aligned} &\varepsilon\left(\bar{x}_2^2/2 + V(x_1)\right) + \mu\varepsilon^{p+1}(h^1(x_1,\bar{x}_2,\theta) + \partial_\theta S^1(x_1,\bar{x}_2,\theta)) \\ &\qquad + \mu\varepsilon^{p+2}(\bar{x}_2\partial_1 S^1(x_1,\bar{x}_2,\theta) + \partial_\theta S^2(x_1,\bar{x}_2,\theta)) + \mathcal{R}_1(x_1,\bar{x}_2,\theta,\mu,\varepsilon), \\ &= \varepsilon\left(\bar{x}_2^2/2 + V(x_1)\right) + \mu\varepsilon^{p+2} V'(x_1)\partial_2 S^1(x_1,\bar{x}_2,\theta) + \mathcal{R}_1(x_1,\bar{x}_2,\theta,\mu,\varepsilon), \end{aligned} \tag{3.4}$$

with $\mathcal{R}_1(x_1,\bar{x}_2,\theta,\mu,\varepsilon) = \mu^2\varepsilon^{2p+2}\partial_2 h^1(x_1,\bar{x}_2,\theta)\partial_1 S^1(x_1,\bar{x}_2) + \mathrm{O}(\mu\varepsilon^{p+3})$. Now, inverting

$$\bar{x}_1 = \partial_2 S(x_1,\bar{x}_2,\theta) = x_1 + \mu\varepsilon^{p+1}\partial_2 S^1(x_1,\bar{x}_2,\theta) + \mu\varepsilon^{p+2}\partial_2 S^2(x_1,\bar{x}_2,\theta),$$

we get an expression for $x_1$

$$x_1 = \bar{x}_1 - \mu\varepsilon^{p+1}\partial_2 S^1(\bar{x}_1, \bar{x}_2, \theta) + \mathrm{O}(\mu\varepsilon^{p+2}),$$

which substituted together with (3.4) in the equation for $\varepsilon\mathcal{H}$, reads as

$$\varepsilon\mathcal{H}(\bar{x}, \theta, \mu, \varepsilon) = \varepsilon\left(\bar{x}_2^2/2 + V(\bar{x}_1)\right) + \mathcal{R}_2(\bar{x}_1, \bar{x}_2, \theta, \mu, \varepsilon),$$

with $\mathcal{R}_2 = \mu^2\varepsilon^{2p+2}\partial_2 h^1 \partial_1 S^1 + \mathrm{O}(\mu\varepsilon^{p+3})$.

It only remains to see that $\mu^2\varepsilon^{2p+2}\partial_2 h^1\partial_1 S^1 = \mathrm{O}(\mu\varepsilon^{p+3})$. We distinguish two cases: $\ell \geq 1$ or $\ell = 0$. If $\ell \geq 1$, then $\gamma = p - \ell \geq 0$ implies $p \geq \ell \geq 1$, and $\mu^2\varepsilon^{2p+2}\partial_2 h^1\partial_1 S^1 = \mathrm{O}(\mu^2\varepsilon^{p+3}) = \mathrm{O}(\mu\varepsilon^{p+3})$. If $\ell = 0$, this means that we are dealing with the special case $h^1(x, \theta) = x_1 g(\theta)$ of the trigonometric case of hypothesis *H3*, (see remark *R3*), i.e., $h^1$ does not depend on $x_2$ and then $\mu^2\varepsilon^{2p+2}\partial_2 h^1\partial_1 S^1 = 0$. □

**Remark 3.2** It could seem a good idea to average the original Hamiltonian $h$ in order to increase the order of the perturbation term (in fact it was $\mathrm{O}(\mu\varepsilon^p)$, and after the averaging it becomes $\mathrm{O}(\mu\varepsilon^{p+2})$). The question now is when to stop this process. The Hamiltonian we have obtained after two steps of averaging has the same integrable part, but the perturbation term $\mathcal{R}$ has no zero mean. If we average again, the new Hamiltonian will have another integrable part with a different separatrix that will depend on $\varepsilon$. This separatrix can have a different kind of singularity and hypotheses *H1-H3* can change drastically.

The averaged Hamiltonian $\mathcal{H}$ has the same integrable part $h^0$ as $h$, but the perturbation term is now $\mathrm{O}(\mu\varepsilon^{p+2})$. We will see that this order of perturbation is preserved when one considers the Birkhoff normal form of $\mathcal{H}$. First of all let us seek for the periodic orbit of $\mathcal{H}$.

**Lemma 3.3** *The Hamiltonian system of Hamiltonian $\varepsilon\mathcal{H}$ has a hyperbolic $2\pi$-periodic orbit $\bar{\gamma}_p(\theta) = (\bar{\gamma}_1(\theta), \bar{\gamma}_2(\theta))$, which is $\mathrm{O}(\mu\varepsilon^{p+2})$.*

*Proof.* In order to check this lemma, we only need to consider the Poincaré map associated to the $2\pi$-periodic Hamiltonian system associated to $\varepsilon\mathcal{H}$. For $\mu\varepsilon^{p+2} = 0$ the origin is a hyperbolic fixed point that is preserved for $\mu\varepsilon^{p+2}$ small enough. This new fixed point gives rise to the hyperbolic $2\pi$-periodic orbit $\bar{\gamma}_p$. For a explicit construction of $\bar{\gamma}_p$ see [DS92]. □

In order to study the local behaviour of the orbits near $\bar{\gamma}_p$ we perform the canonical change of variables

$$y = \bar{x} - \bar{\gamma}_p(\theta), \tag{3.5}$$

that sends the periodic orbit to the origin, and we obtain again a Hamiltonian system of Hamiltonian $\varepsilon k$, with

$$k(y, \theta, \mu, \varepsilon) = h^0(y) + \mu\varepsilon^{p+2}\mathcal{K}(y, \theta, \mu, \varepsilon) = \frac{y_2^2}{2} - \frac{(\omega^0 y_1)^2}{2} + \mathrm{O}(y^3, \mu\varepsilon^{p+2}),$$

which is transformed into its normal form up to order two in the following lemma.

**Lemma 3.4** *There exists a canonical change of variables*

$$Y \longmapsto y = A(\theta, \mu, \varepsilon)Y \tag{3.6}$$

*linear in* $Y$ *and* $2\pi$*-periodic and* $\mathcal{C}^2$ *in* $\theta$*, with* $A = A^0 + \mathrm{O}(\mu\varepsilon^{p+2})$*, where*

$$A^0 = \frac{1}{2}\begin{pmatrix} 2/c & -c/\omega^0 \\ 2\omega^0/c & c \end{pmatrix}, \tag{3.7}$$

$c \neq 0$ *being an arbitrary constant, such that transforms the Hamiltonian system associated to* $\varepsilon k$ *into a Hamiltonian system whose Hamiltonian* $\varepsilon K$ *is in normal form up to order 2:*

$$K(Y, \theta, \mu, \varepsilon) = K^0(Y) + \mu\varepsilon^{p+2}K^1(Y, \theta, \mu, \varepsilon) = \omega Y_1 Y_2 + \mathrm{O}(Y^3),$$

*with* $\omega = \omega^0 + \mathrm{O}(\mu\varepsilon^{p+2})$.

*Proof.* It follows directly from Floquet theory applied to the linear part of the Hamiltonian system associated to $\varepsilon k$. In fact, the unperturbed change of variables $y = A^0 Y$, with $A^0$ given in (3.7), transforms the unperturbed Hamiltonian $h^0(y)$ in its normal form up to order two, i.e.,

$$h^0(y) = K^0(Y) = \omega^0 Y_1 Y_2 + \mathrm{O}(Y^3).$$

□

The Hamiltonian $K$ is now ready to perform on it the nonlinear normal form, which in this case is convergent in a neighbourhood of the origin $Y = 0$ with a radius that does not depend on $\mu$, $\varepsilon$.

**Proposition 3.5** *There exist* $R_0 > 0$*, independent of* $\mu$*,* $\varepsilon$*, and a canonical change of variables:*

$$Y = \Phi(X, \theta, \mu, \varepsilon) = \Phi^0(X) + \mu\varepsilon^{p+2}\Phi^1(X, \theta, \mu, \varepsilon), \tag{3.8}$$

*analytic with respect to* $X$ *for* $\|X\|^2 < R_0^2$ *and* $2\pi$*-periodic and* $\mathcal{C}^2$ *in* $\theta$*, and that verifies*

$$\Phi(X, \theta, \mu, \varepsilon) = X + \mathrm{O}(X^2), \qquad \Phi^0(X) = X + \mathrm{O}(X^2), \tag{3.9}$$

*such that transforms the Hamiltonian system associated to* $\varepsilon K$ *into the Hamiltonian system generated by a Hamiltonian* $\varepsilon H$ *in normal form*

$$H(X, \theta, \mu, \varepsilon) = F(X_1 X_2, \mu, \varepsilon) = F^0(X_1 X_2) + \mu\varepsilon^{p+2}F^1(X_1 X_2, \mu, \varepsilon),$$

*with* $F(I) = \omega I + \mathrm{O}(I^2)$.

*Proof.* The existence of such a canonical change of variables is a very well known result, due to Moser [Mos56]. It is not difficult to check in that proof that the dependence of the Hamiltonian on $\varepsilon$ gives a radius of convergence of the normal form that can be bounded from below by a constant independent of $\mu$ and $\varepsilon$.

Notice also that the unperturbed change $\Phi^0(X)$ transforms the system associated to $K^0(Y)$ into its normal form, which is the system associated to $F^0(X_1 X_2)$. □

Now the proof of Theorem 2.1 is clear if we compose all the changes given by (3.2), (3.5), (3.6) and (3.8), and the change of time $\theta = t/\varepsilon$. □

## Proof of Corollary 2.2

By Theorem 2.1, the canonical change of variables (2.2) transforms the original system (1.2) into its normal form given by system (2.4). Then all the results we can get near the origin of system (2.4) can be transported to (1.2) using this change. More specifically we will work in $W = \{X \in \mathbf{C}^2 : \|X\|^2 \leq R_0^2\}$, and then we will obtain results in $\{(x,\theta) \in \mathbf{C}^2 \times \mathbf{R} : \|x - \gamma_p(\theta)\| < r_0^2\}$, with $r_0$ independent of $\mu$, $\varepsilon$,

For the proof of this corollary we only need to consider the branch of the stable manifold of system (2.4) given by $(0,\, \mathrm{e}^{-\omega t} X_2^{\mathrm{s}})$, where $X_2^{\mathrm{s}} > 0$. Introducing $s + c^{\mathrm{s}} = -\frac{1}{\omega} \log X_2^{\mathrm{s}}$, it can be parameterized by

$$X^{\mathrm{s}}(t,s) = \left(0,\, \mathrm{e}^{-\omega(t+s+c^{\mathrm{s}})}\right). \tag{3.10}$$

The unstable manifold can be parameterized analogously by

$$X^{\mathrm{u}}(t,s) = \left(\mathrm{e}^{\omega(t+s+c^{\mathrm{u}})}, 0\right). \tag{3.11}$$

In fact all the parameters that appear in these formulae are not independent but we will fix them later on. In order to transport all these parameterizations to the original system (1.2), we only need to compose them with the change of variables (2.2), and thus we obtain

$$\begin{aligned} x^{\mathrm{u}}(t,s) &= \Psi(\,\mathrm{e}^{\omega(t+s+c^{\mathrm{u}})}, 0, t/\varepsilon), \quad \Re(t+s+c^{\mathrm{u}}) \leq -T^0, & (3.12)\\ x^{\mathrm{s}}(t,s) &= \Psi(0,\, \mathrm{e}^{-\omega(t+s+c^{\mathrm{s}})}, t/\varepsilon), \quad \Re(t+s+c^{\mathrm{s}}) \geq T^0, & (3.13) \end{aligned}$$

with $T^0 = \ln R_0/\omega$ chosen in such a way that $X^{\mathrm{u}}(t,s)$, $X^{\mathrm{s}}(t,s)$ belong to $W$ for the range of parameters $(t,s)$ of (3.12) and (3.13).

It is straightforward to see that parameterizations (3.12) and (3.13) verify:

$$x^*(t + 2\pi\varepsilon, s) = x^*(t, s + 2\pi\varepsilon) \quad * = \mathrm{s}, \mathrm{u}.$$

as a consequence of the $2\pi\varepsilon$-periodicity of the change (2.2).

Now, we will choose the constants $c^{\mathrm{s}}$, $c^{\mathrm{u}}$ in order to establish estimate (2.9). In fact, by hypothesis *H1*, $x^0(u)$ is a homoclinic connection for the integrable case ($\mu = 0$). It seems natural to choose the constants in such a way that the parameterizations (3.12) and (3.13) are both equal to this one when $\mu = 0$.

By the proof of Theorem 2.1, and more precisely by (3.7) and (3.9), the change (2.2) for $\mu = 0$ can be written in vector notation as

$$x = \Psi^0(X) = A^0 \Phi^0(X) = A^0(X + \mathrm{O}(X^2)) = A^0 X + \mathrm{O}(X^2),$$

so that using (3.11) for $\mu = 0$, the unstable manifold for $(t,s)$ as in (3.12) is given in components by

$$x^{u,0}(t,s) = \left(\frac{\mathrm{e}^{\omega^0(t+s+c^{\mathrm{u}})}}{c}, \frac{\omega^0\, \mathrm{e}^{\omega^0(t+s+c^{\mathrm{u}})}}{c}\right) + \mathrm{O}(\,\mathrm{e}^{2\omega^0(t+s+c^{\mathrm{u}})}),$$

where $c$ is the constant that appears in the matrix $A^0$ given in (3.7), whereas using (3.10) for $\mu = 0$, the stable manifold for the set $(t, s)$ as in (3.13) is given in components by

$$x^{s,0}(t,s) = \left(-\frac{c}{2\omega^0}\,\mathrm{e}^{-\omega^0(t+s+c^{\mathrm{s}})}, \frac{c}{2}\,\mathrm{e}^{-\omega^0(t+s+c^{\mathrm{s}})}\right) + \mathrm{O}(\,\mathrm{e}^{-2\omega^0(t+s+c^{\mathrm{s}})}).$$

On the other hand, since the origin of the unperturbed system is hyperbolic, the asymptotics of the separatrix $x^0(t+s)$ near the origin are given by

$$\begin{aligned} x^0(t+s) &= (k^{\mathrm{u}}\,\mathrm{e}^{\omega^0(t+s)}, \omega^0 k^{\mathrm{u}}\,\mathrm{e}^{\omega^0(t+s)}) + \mathrm{O}(\,\mathrm{e}^{2\omega^0(t+s)}), && t+\Re s \to -\infty, \\ x^0(t+s) &= (k^{\mathrm{s}}\,\mathrm{e}^{-\omega^0(t+s)}, -\omega^0 k^{\mathrm{s}}\,\mathrm{e}^{-\omega^0(t+s)}) + \mathrm{O}(\,\mathrm{e}^{-2\omega^0(t+s)}), && t+\Re s \to \infty, \end{aligned}$$

so we fix the constants to verify the conditions

$$-\frac{c}{2\omega^0}\,\mathrm{e}^{-\omega^0 c^{\mathrm{s}}} = k^{\mathrm{s}}, \qquad \frac{1}{c}\,\mathrm{e}^{\omega^0 c^{\mathrm{u}}} = k^{\mathrm{u}}.$$

We have some freedom in order to choose the constants. We will fix $c^{\mathrm{s}} = 0$, and the other ones are then fixed. Introducing $T/2 \geq T^0 + c^{\mathrm{u}}, T^0$, the manifolds defined in (3.12) and (3.13) are also defined for $(t, s)$ in (2.7) and (2.8).

Coming back to the case $\mu \neq 0$, we can use the form (2.3) of the change (2.2) to write the local unstable manifold for $(t, s)$ verifying (2.7) as

$$\begin{aligned} x^{\mathrm{u}}(t,s) &= \Psi(\,\mathrm{e}^{\omega(t+s+c^{\mathrm{u}})}, 0, t/\varepsilon) \\ &= \Psi^0(\,\mathrm{e}^{\omega(t+s+c^{\mathrm{u}})}, 0) + \mu\varepsilon^{p+1} G(\Psi^0(\,\mathrm{e}^{\omega(t+s+c^{\mathrm{u}})}, 0), t/\varepsilon) + \mathrm{O}(\mu\varepsilon^{p+2}), \end{aligned}$$

and an analogous expression for the local stable one for $(t, s)$ verifying (2.8).

Since $\omega = \omega^0 + \mathrm{O}(\mu\varepsilon^{p+2})$, we can assume that $|\omega - \omega_0| < 1/2$, restricting $\mu_0$ if necessary, and hence

$$\left|\,\mathrm{e}^{\omega_0(t+s)} - \,\mathrm{e}^{\omega(t+s)}\right| < c'\,|\omega - \omega_0|\,\,\mathrm{e}^{(t+\Re s)/2}$$

for $t + \Re s < -T/2$, with $c'$ depending only on $T$. In this way we now obtain the estimate (2.9) for the local unstable manifold. The estimate (2.9) for the local stable one is obtained analogously.

The asymptotics (2.10) for $W^*_{\mathrm{loc}}(\gamma_p)$ are obtained in the same way, using that $\gamma_p(\theta) = \Psi(0, \theta)$, as well as Taylor's Theorem. □

## Proof of Corollary 2.3

First of all, solving explicitly system (2.4), it is easy to check that the following change of variables

$$\begin{aligned} \Omega : U &\longrightarrow \mathbf{C}^2 \\ X = (X_1, X_2) &\longmapsto (S, E) = (-\log X_2 / F'(X_1 X_2), F(X_1 X_2)), \end{aligned} \tag{3.14}$$

defined on the open set $U = \{(X_1, X_2) \in W : \quad X_2 > 0\}$, provides the flow-box coordinates, which are $\mathrm{O}(\mu\varepsilon^{p+2})$-close, by (2.5), to the flow box coordinates of the unperturbed case $\mu = 0$:

**Lemma 3.6** *1. The change (3.14) transforms system (2.4) into system (2.12).*

*2. The inverse change $\Xi$ is defined in $\mathcal{V} = \Omega(U)$, and is given by*

$$\begin{array}{rcl} \Xi : \mathcal{V} & \longrightarrow & U \\ (S, E) & \longmapsto & (X_1, X_2) = \left( \mathrm{e}^{F'(F^{-1}(E))S} \cdot F^{-1}(E),\, \mathrm{e}^{-F'(F^{-1}(E))S} \right). \end{array} \tag{3.15}$$

*3. Both changes of variables given by (3.14) and (3.15) are canonical.*

*4. Let $\Omega^0$, $\Xi^0$ be the changes (3.14) and (3.15) corresponding to the unperturbed system associated to (2.5). Then*

$$\Omega(X) = \Omega^0(X) + \mathrm{O}(\mu\varepsilon^{p+2}), \qquad \Xi(S, E) = \Xi^0(S, E) + \mathrm{O}(\mu\varepsilon^{p+2}), \tag{3.16}$$

*for $X \in U$ and $(S, E) \in \mathcal{V}$.*

The change (2.11) is constructed simply by composing the change (3.14) with the inverse $\Psi^{-1}$ of the change $\Psi$ given by (2.2), restricting $\mathcal{V}$ if necessary:

$$(\mathcal{S}(x, t/\varepsilon), \mathcal{E}(x, t/\varepsilon)) = \Omega(\Psi^{-1}(x, t/\varepsilon)),$$

and equalities (2.13) are a consequence of (3.16) and (2.3).

The inverse change is obtained composing the change $\Psi$ with the change (3.15):

$$\mathcal{X}(S, E, t/\varepsilon) = \Psi(\Xi(S, E), t/\varepsilon),$$

and verifies (2.14), also as a consequence of (3.16) and (2.3).

Finally, from parameterization (3.13) of the 2-dimensional local stable manifold of $\gamma_p$ for $(t, s)$ in (2.8), and taking into account that we have chosen $c^{\mathrm{s}} = 0$ along the proof of Corollary 2.2, it is clear that

$$(\mathcal{S}(x^{\mathrm{s}}(t, s), t/\varepsilon), \mathcal{E}(x^{\mathrm{s}}(t, s), t/\varepsilon)) = \Omega(0,\, \mathrm{e}^{-\omega(t+s)}) = (t + s, 0),$$

i.e., we have obtained formulae (2.15). □

# 4 Proof of the Extension Theorem

## 4.1 Notation

Along this proof, $s$ is the complex parameter in the strip $|\Im s| \leq a - \varepsilon$, $t$ is the real time for $|t + \Re s| \leq T$, and $0 < \tau = |t + s - a\,\mathrm{i}| = ((t + \Re s)^2 + (\Im s - a)^2)^{1/2}$, $\tau_0 = |t_0 + s - a\,\mathrm{i}|$, $\tau_1 = |t_1 + s - a\,\mathrm{i}|$. For $v(t) \in \mathbf{C}^2$, we introduce

$$|v(t)|_\tau = |v_1(t)| + |v_2(t)|\,\tau. \tag{4.1}$$

$\varepsilon > 0$ and $\mu$ will denote small independent parameters: $0 < \varepsilon < \varepsilon_0$, $|\mu| < \mu_0$, and $K = K(a, T, t_0)$ will denote a generic positive constant independent of $\varepsilon$ and $\mu$.

## 4.2 Set up

To compare the solution $x(t,s)$ of the full system with the homoclinic solution $x^0(t+s)$ of the unperturbed system (1.1) we introduce:

$$\xi(t) = \xi(t,s) := x(t,s) - x^0(t+s).$$

The system of differential equations satisfied by $\xi(t)$ with respect to the variable $t$ is written in components as:

$$\begin{aligned}
\dot{\xi}_1 &= \xi_2 + \mu\varepsilon^p \partial_2 h^1 \left(x^0(t+s) + \xi, t/\varepsilon\right), \\
\dot{\xi}_2 &= f\left(x_1^0(t+s) + \xi_1\right) - f\left(x_1^0(t+s)\right) - \mu\varepsilon^p \partial_1 h^1 \left(x^0(t+s) + \xi, t/\varepsilon\right),
\end{aligned}$$

and it is standard to write it as:

$$\dot{\xi} = A(t+s)\xi + \mu\varepsilon^p g\left(x^0(t+s), t/\varepsilon\right) + F\left(\xi, t+s, t/\varepsilon\right), \tag{4.2}$$

where $g = (\partial_2 h^1, -\partial_1 h^1)^T$, $A(u)$ is the matrix

$$A(u) = \begin{pmatrix} 0 & 1 \\ f'\left(x_1^0(u)\right) & 0 \end{pmatrix}, \tag{4.3}$$

and the function $F(\xi, u, t/\varepsilon)$, which depends also on $\mu\varepsilon^p$, is given by:

$$\begin{aligned}
F\left(\xi, u, t/\varepsilon\right) &= \begin{pmatrix} 0 \\ f\left(x_1^0(u) + \xi_1\right) - f\left(x_1^0(u)\right) - f'\left(x_1^0(u)\right) \cdot \xi_1 \end{pmatrix} \\
&\quad + \mu\varepsilon^p \left[g\left(x^0(u) + \xi, t/\varepsilon\right) - g\left(x^0(u), t/\varepsilon\right)\right].
\end{aligned}$$

We first look for an equivalent integral equation for the solutions $\xi(t)$ of system (4.2) with initial condition

$$\xi(t_0) = \mu\varepsilon^{p+1} G\left(x^0(t_0+s), t_0/\varepsilon\right) + \mathrm{O}(\mu\varepsilon^{p+2}), \tag{4.4}$$

which is the translation of hypothesis (2.17) on $x(t_0, s)$. For this purpose, we first seek for a fundamental matrix of the corresponding homogeneous linear system

$$\frac{\mathrm{d}\xi}{\mathrm{d}u} = A(u)\xi. \tag{4.5}$$

A solution of (4.5) is simply $\dot{x}^0(u)$. Another independent solution can be obtained in the form: $\xi_1(u) = x_2^0(u) \cdot W(u)$, $\xi_2 = \xi_1' := \mathrm{d}\xi_1/\mathrm{d}u$ with

$$W(u) = \int_b^{\mathrm{u}} \frac{\mathrm{d}v}{x_2^0(v)^2}, \tag{4.6}$$

with $b \in \mathbf{C}$ momentarily arbitrary, to be fixed later on. Introducing:

$$\begin{aligned} \Psi(u) &= x_2^0(u) = \dot{x}_1^0(u), \\ \Phi(u) &= x_2^0(u)W(u) = \Psi(u)W(u), \end{aligned}$$

it is easy to see that $\Psi(u)\Phi'(u) - \Phi(u)\Psi'(u) = (x_2^0)^2(u)W'(u) = 1$, and that a fundamental matrix of (4.5) is $M(u)$, where:

$$M(u) = \begin{pmatrix} \Psi(u) & \Phi(u) \\ \Psi'(u) & \Phi'(u) \end{pmatrix}, \tag{4.7}$$

and hence the fundamental solution $\varphi(u,\sigma)$ of (4.5) satisfying $\varphi(u,u) =$Id is given by $\varphi(u,\sigma) = M(u)M(\sigma)^{-1}$, where

$$M(u)^{-1} = \begin{pmatrix} \Phi'(u) & -\Phi(u) \\ -\Psi'(u) & \Psi(u) \end{pmatrix}.$$

Using this fundamental solution of the linear equation (4.5), we can easily write the solution $\xi(t)$ of system (4.2) with initial condition $\xi(t_0)$ as:

$$\xi(t) = \xi^1(t) + M(t+s)\int_{t_0}^{t} M(\sigma+s)^{-1} F\left(\xi(\sigma), \sigma+s, \sigma/\varepsilon\right) \mathrm{d}\sigma, \tag{4.8}$$

with

$$\xi^1(t) := M(t+s)\left[M(t_0+s)^{-1}\xi(t_0) + \mu\varepsilon^p \int_{t_0}^{t} M(\sigma+s)^{-1} g(x^0(\sigma+s), \sigma/\varepsilon)\,\mathrm{d}\sigma\right].$$

By hypothesis *H3*, $g$ has zero mean (with respect to $\theta$), and consequently there exists $G(x,\theta)$ with zero mean such that $\partial_\theta G = g$ ($G$ is already introduced in formulae (2.1)), and therefore $\mathcal{G}(x,\theta)$ such that $\partial_\theta \mathcal{G} = G$. Introducing

$$m(u,\theta) := M(u)^{-1}\mathcal{G}(x^0(u),\theta), \tag{4.9}$$

the expression above for $\xi^1(t)$ takes the form

$$\xi^1(t) = M(t+s)\left[M(t_0+s)^{-1}\xi(t_0) + \mu\varepsilon^p \int_{t_0}^{t} \partial_\theta^2 m(\sigma+s, \sigma/\varepsilon)\,\mathrm{d}\sigma\right].$$

Using the identity

$$\partial_\theta^2 m(\sigma+s,\sigma/\varepsilon) - \varepsilon^2 m''(\sigma+s,\sigma/\varepsilon) = \frac{\mathrm{d}}{\mathrm{d}\sigma}\left[\varepsilon\partial_\theta m(\sigma+s,\sigma/\varepsilon) - \varepsilon^2 m'(\sigma+s,\sigma/\varepsilon)\right],$$

where $m'$ denotes $\partial m/\partial u$, as well as $\partial_\theta m(u,\theta) = M(u)^{-1}G(x^0(u),\theta)$, we can finally write $\xi^1(t)$ as

$$\begin{aligned} \xi^1(t) &= \mu\varepsilon^{p+1} G(x^0(t+s), t/\varepsilon) \\ &\quad + M(t+s)\left[M(t_0+s)^{-1}\left(\xi(t_0) - \mu\varepsilon^{p+1}G(x^0(t_0+s), t_0/\varepsilon)\right)\right. \\ &\quad \left. - \mu\varepsilon^{p+2}\left(m'(t+s,t/\varepsilon) - m'(t_0+s,t_0/\varepsilon) - \int_{t_0}^{t} m''(\sigma+s,\sigma/\varepsilon)\,\mathrm{d}\sigma\right)\right]. \end{aligned} \tag{4.10}$$

## 4.3 Preliminary bounds

Now we have a suitable expression (4.8), (4.10) for $\xi$ to carry out an iterative process. Before proceeding with it, we need to bound the fundamental matrix $M(u)$, as well as the functions $f$, $g$ and $F$.

To get a well behaved fundamental matrix $M(u)$ near the singularity of $x^0(u)$, it is very important to choose adequately the parameter $b$ that is still free in the definition (4.6) of $W(u)$.

We will consider first the case $0 \leq \Im u \leq a$. On the upper boundary of this strip, by hypothesis *H2*, $x_2^0(u)$ has a pole of order $r$ ($r \geq 1$) at the point $u = a\,\mathrm{i}$:

$$x_2^0(u) = \dot{x}_1^0(u) = \frac{\mathrm{C}}{(u - a\,\mathrm{i})^r}(1 + \mathrm{O}(u - a\,\mathrm{i})), \qquad \mathrm{C} \neq 0,$$

and because of this, we will choose precisely $b = a\,\mathrm{i}$. In this way, $W(u)$ has a zero of multiplicity $2r + 1$ at $u = a\,\mathrm{i}$, $y_0(u) \cdot W(u)$ has a zero of multiplicity $r + 1$ at $u = a\,\mathrm{i}$, and hence

$$\begin{aligned} \Psi(u) &= \frac{\mathrm{C}}{(u - a\,\mathrm{i})^r}(1 + \mathrm{O}(u - a\,\mathrm{i})), \\ \Phi(u) &= \frac{1}{(2r+1)\mathrm{C}}(u - a\,\mathrm{i})^{r+1}(1 + \mathrm{O}(u - a\,\mathrm{i})), \end{aligned}$$

and as a consequence, the fundamental matrix (4.7) behaves near the pole as:

$$M(u) \sim \begin{pmatrix} \dfrac{\mathrm{C}}{(u - a\,\mathrm{i})^r} & \dfrac{1}{(2r+1)\mathrm{C}}(u - a\,\mathrm{i})^{r+1} \\ \dfrac{-r\mathrm{C}}{(u - a\,\mathrm{i})^{r+1}} & \dfrac{(r+1)}{(2r+1)\mathrm{C}}(u - a\,\mathrm{i})^r \end{pmatrix}.$$

From the expressions above, next lemma follows directly.

**Lemma 4.1** *For $|t + \Re s|, |t_1 + \Re s| \leq T$, $0 \leq \Im s < a$, the following bounds hold:*

$$\left|\Psi^{(k)}(t+s)\right| \leq \frac{K}{\tau^{r+k}}, \qquad \left|\Phi^{(k)}(t+s)\right| \leq K\tau^{r+1-k}, \quad k = 0, 1, 2,$$

$$|M(t+s)v(t)|_\tau \leq K\left(\frac{|v_1(t)|}{\tau^r} + \tau^{r+1}\,|v_2(t)|\right), \tag{4.11}$$

$$\left|M(t+s)M(t_1+s)^{-1}v(t_1)\right|_\tau \leq K\,|v(t_1)|_{\tau_1}\left(\frac{\tau_1^r}{\tau^r} + \frac{\tau^{r+1}}{\tau_1^{r+1}}\right), \tag{4.12}$$

*for every $v(t), v(t_1) \in \mathbf{C}^2$, where $|v(t)|_\tau := |v_1(t)| + |v_2(t)|\,\tau$, $\tau := |t + s - a\,\mathrm{i}|$, and $|v(t_1)|_{\tau_1} := |v_1(t_1)| + |v_2(t_1)|\,\tau_1$, $\tau_1 := |t_1 + s - a\,\mathrm{i}|$, as introduced in (4.1).*

To bound $f$, $g$ and $F$ on $x = x^0(t + s)$, we rely strongly on hypotheses *H2* and *H3*. By the (trigonometric) polynomial character of $f$ (see remark *R2*), and due to the fact

that $f(x_1^0(u)) = \ddot{x}_1^0(u)$ has a pole of order $r+1$ at $u = a\,\mathrm{i}$, we get for $|t + \Re s| \le T$, $0 \le \Im s \le a$:

$$\left|f^{(N)}(x_1^0(t+s))\right| \le \frac{K}{\tau^{r+1-N(r-1)}} = \frac{K}{\tau^{2-(N-1)(r-1)}}, \qquad N \ge 0. \tag{4.13}$$

By hypothesis *H3*, $h^1$ is a (trigonometric) polynomial in $x_1$ and a polynomial in $x_2$, and all the monomies in $x$ of $h^1(x,\theta)$ when evaluated on $x = x^0(u)$ have at most a pole of order $\ell$ at $u = a\,\mathrm{i}$. Consequently, on $|t + \Re s| \le T$, $0 \le \Im s \le a$,

$$\left|\partial_1^{N_1}\partial_2^{N_2} h^1(x^0(t+s), t/\varepsilon)\right| \le \frac{K}{\tau^{\ell - N_1(r-1) - N_2 r}}, \qquad N_1, N_2 \ge 0. \tag{4.14}$$

From the bounds above on the derivatives of $f$ and $h^1$, we get readily the following required bounds for $f$, $g$ and $F$, simply applying Taylor's Theorem, and using notation (4.1).

**Lemma 4.2** *For $\xi^j = \xi^j(t)$, $j = 1, 2$, such that $|\xi^j|_\tau \le \eta(\tau) \le \delta/\tau^{r-1}$, with $\delta < 1$, the following bounds hold on $|t + \Re s| \le T$, $0 \le \Im s \le a$, with $\varepsilon \le \tau = |t + s - a\,\mathrm{i}| \le T$:*

$$\begin{aligned}
\left|f\left(x_1^0(t+s) + \xi_1^1\right) - f\left(x_1^0(t+s) + \xi_1^2\right)\right| &\le \frac{K\,|\xi_1^1 - \xi_1^2|}{\tau^2}, \\
\left|g\left(x^0(t+s) + \xi^1, t/\varepsilon\right) - g\left(x^0(t+s) + \xi^2, t/\varepsilon\right)\right|_\tau &\le \frac{K\,|\xi^1 - \xi^2|_\tau}{\tau^{\ell-2r+1}}, \\
\left|F\left(\xi^1, t+s, t/\varepsilon\right) - F\left(\xi^2, t+s, t/\varepsilon\right)\right|_\tau &\le K\left(\frac{\mu\varepsilon^p}{\tau^{\ell-2r+1}} + \frac{\eta(\tau)}{\tau^{2-r}}\right)\left|\xi^1 - \xi^2\right|_\tau.
\end{aligned} \tag{4.15}$$

Finally, here comes the last technical lemma that will be needed later on.

**Lemma 4.3** *For $t$, $t_0$, $\beta$ real, $s$ complex, such that*

$$0 \le \Im s < a, \quad -T \le t_0 + \Re s \le t + \Re s \le T,$$

*let us denote*

$$\rho^{-\beta}_{[t_0,t]}(s) := \begin{cases} \sup \dfrac{1}{|\sigma + s - a\,\mathrm{i}|^\beta}, & \text{if } \beta \ne 0, \\ \sup \left|\ln(|\sigma + s - a\,\mathrm{i}|)\right|, & \text{if } \beta = 0, \end{cases}$$

*where the supremum is taken on $\sigma \in [t_0, t]$.*

*Then, there exists $K = K(a, t_0, T, \beta) > 0$ such that the following inequalities hold:*

$$\int_{t_0}^t \frac{\mathrm{d}\sigma}{|\sigma + s - a\,\mathrm{i}|^\beta} \le K \cdot \rho^{-(\beta-1)}_{[t_0,t]}(s), \tag{4.16}$$

$$\left|M(t+s)\int_{t_0}^t M(\sigma+s)^{-1} v(\sigma)\,\mathrm{d}\sigma\right|_\tau \le K\mathrm{C}\left(\frac{\rho^{-(\beta-r-1)}_{[t_0,t]}(s)}{\tau^r} + \tau^{r+1}\rho^{-(\beta+r)}_{[t_0,t]}(s)\right), \tag{4.17}$$

*where $\tau = |t + s - a\,\mathrm{i}|$ and $v(t) \in \mathbf{C}^2$ is such that*

$$|v(t)|_\tau := |v_1(t)| + |v_2(t)|\,\tau \le \mathrm{C}/\tau^\beta. \tag{4.18}$$

The proof of (4.16) is straightforward (and can be found in [Lemma 7.1] Bound (4.17) for functions $v(t) \in \mathbf{C}^2$ satisfying (4.18) follows readily from (4.12) and (4.16).

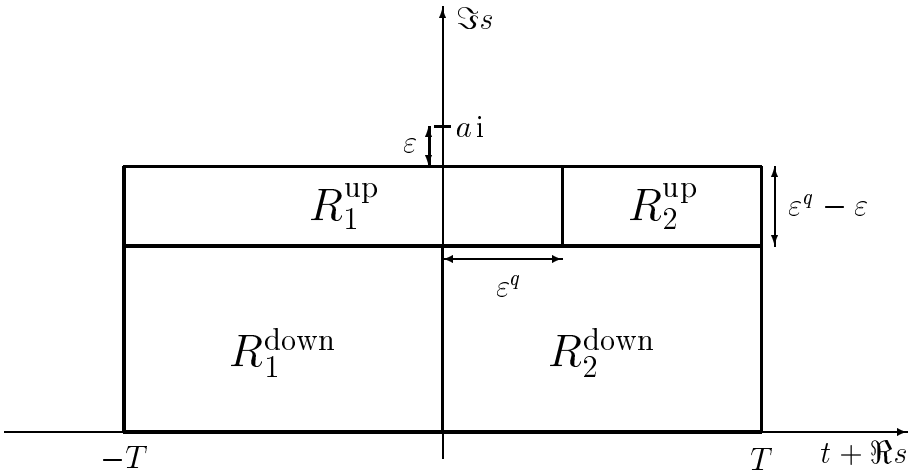

Figure 1: Domains $D_1 = R_1^{\mathrm{up}} \cup R_1^{\mathrm{down}}$, $D_2 = R_2^{\mathrm{up}} \cup R_2^{\mathrm{down}}$.

## 4.4 Partition of the domain

The proof of the Extension Theorem, for the moment for $0 \leq \Im s \leq a - \varepsilon$, is based on the following two propositions. In the first one, the solutions of system (4.2) with initial conditions (4.4) will be extended for $(t, s) \in D_1 := R_1^{\mathrm{up}} \cup R_1^{\mathrm{down}}$, where $R_1^{\mathrm{up}}$, $R_1^{\mathrm{down}}$ are the rectangles given by the equations (see figure 1)

$$\begin{aligned} R_1^{\mathrm{up}}: &\quad -T \leq t + \Re s \leq \varepsilon^q, \quad a - \varepsilon^q \leq \Im s \leq a - \varepsilon, \\ R_1^{\mathrm{down}}: &\quad -T \leq t + \Re s \leq 0, \quad 0 \leq \Im s \leq a - \varepsilon^q, \end{aligned}$$

where $-T := t_0 + \Re s$ and $q = (r+1)/(2r+1)$. Since $r \geq 1$, then $1/2 < q \leq 2/3$. In the second proposition, we take the separation point $t = t_1(s)$:

$$t_1 + \Re s := \begin{cases} \varepsilon^q, & \text{for} \quad a - \varepsilon^q \leq \Im s \leq a - \varepsilon, \\ 0, & \text{for} \quad\quad 0 \leq \Im s \leq a - \varepsilon^q, \end{cases} \tag{4.19}$$

as the initial time, and these solutions of system (4.2) will be extended for $(t, s) \in D_2 := R_2^{\mathrm{up}} \cup R_2^{\mathrm{down}}$, where $R_2^{\mathrm{up}}$, $R_2^{\mathrm{down}}$ are the rectangles given by the equations

$$\begin{aligned} R_2^{\mathrm{up}}: &\quad \varepsilon^q \leq t + \Re s \leq T, \quad a - \varepsilon^q \leq \Im s \leq a - \varepsilon, \\ R_2^{\mathrm{down}}: &\quad 0 \leq t + \Re s \leq T, \quad 0 \leq \Im s \leq a - \varepsilon^q. \end{aligned}$$

## 4.5 First domain

**Proposition 4.4** *Given $s \in \mathbf{C}$ such that $0 \leq \Im s \leq a - \varepsilon$, let $\xi(t) = \xi(t, s)$ be a solution of system (4.2) with initial condition (4.4) on $t_0 = -T - \Re s$. Then, if $\gamma := p - \ell \geq 0$, the solution $\xi(t)$ can be extended for $t \in [t_0, t_1(s)]$, with $t_1(s)$ given in (4.19), satisfying*

*there the following estimates:*

$$\left|\xi(t) - \mu\varepsilon^{p+1} G(x^0(t+s), t/\varepsilon)\right|_\tau \;\leq\; K\frac{\mu\varepsilon^{\gamma+r+1}}{\tau^r}, \tag{4.20}$$

$$|\xi(t)|_\tau \;\leq\; K\mu\varepsilon^{\gamma+1}. \tag{4.21}$$

*Proof.* We shall use the method of successive approximations. We begin the iteration process with $\xi^0(t) = 0$, and consider for $n \geq 0$ and $t \in [t_0, t_1(s)]$ the recurrence suggested by equation (4.8):

$$\xi^{n+1}(t) = \xi^1(t) + M(t+s)\int_{t_0}^{t} M(\sigma+s)^{-1} F(\xi^n(\sigma), \sigma+s, \sigma/\varepsilon)\,\mathrm{d}\sigma.$$

The first iterate is $\xi^1(t)$, as given by (4.10). The main idea is to check that $\xi^1$ satisfies the required bound (4.20), and that the successive iterates are small enough to preserve it for the limit $\xi$.

There are several terms in the expression (4.10) of $\xi^1(t)$. From the initial condition (4.4) and the fact that $t_0 + s = -T + \Im s$ is far from the singularity $a\,\mathrm{i}$, we get

$$M(t_0+s)^{-1}\left(\xi(t_0) - \mu\varepsilon^{p+1} G(x^0(t_0+s), t_0/\varepsilon)\right) = \mathrm{O}(\mu\varepsilon^{p+2}),$$

and consequently, using (4.11), we can bound one term of (4.10):

$$\left|M(t+s)M(t_0+s)^{-1}\left(\xi(t_0) - \mu\varepsilon^{p+1} G(x^0(t_0+s), t_0/\varepsilon)\right)\right|_\tau \leq K\mu\varepsilon^{p+2}\left[\frac{1}{\tau^r} + \tau^{r+1}\right].$$

For the terms involving $m$, we use definition (4.9): $m = M^{-1}\mathcal{G}$, where for simplicity $\mathcal{G}$ denotes $\mathcal{G}(x^0(u), \theta)$, as well as the fact that $(M^{-1})' = -M^{-1}A$, where $'$ denotes $\partial/\partial u$, to get:

$$m' = M^{-1}(\mathcal{G}' - A\mathcal{G}) =: M^{-1}\mathcal{G}_1, \qquad m'' = M^{-1}(\mathcal{G}_1' - A\mathcal{G}_1) =: M^{-1}\mathcal{G}_2. \tag{4.22}$$

Now, one has to take into account that $G$ and $\mathcal{G}$ have the same kind of bounds (4.14) as $g = (\partial_2 h^1, -\partial_1 h^1)^T$, as well as the definitions of $\mathcal{G}_1$ and $\mathcal{G}_2$ and the form (4.3) of the matrix $A$ to get the bounds:

$$|G|_\tau \leq \frac{K}{\tau^{\ell-r}}, \quad |\mathcal{G}|_\tau \leq \frac{K}{\tau^{\ell-r}}, \quad |\mathcal{G}_1|_\tau \leq \frac{K}{\tau^{\ell-r+1}}, \quad |\mathcal{G}_2|_\tau \leq \frac{K}{\tau^{\ell-r+2}}, \tag{4.23}$$

for $|t + \Re s| \leq T$, $0 \leq \Im s < a$. Here, $|G|_\tau$ denotes $|G_1(x^0(t+s), \theta)| + |G_2(x^0(t+s), \theta)|\,\tau$, according to notation (4.1). Analogously for $|\mathcal{G}|_\tau$, $|\mathcal{G}_1|_\tau$, and $|\mathcal{G}_2|_\tau$.

Using expressions (4.22) for $m'$, $m''$, we now proceed to estimate $\xi^1(t)$ given in (4.10). We simply use bounds (4.23), as well as bounds (4.12) and (4.17), with $\beta = \ell - r + 2$ and $\mathrm{C} = \mu\varepsilon^{p+2}$, to get

$$\begin{aligned}&\left|\xi^1(t) - \mu\varepsilon^{p+1} G(x^0(t+s), t/\varepsilon)\right|_\tau \\ &\quad\leq K\mu\varepsilon^{p+2}\left[\frac{1}{\tau^r} + \tau^{r+1} + \frac{1}{\tau^{\ell-r+1}} + \frac{1}{\tau^r} + \tau^{r+1} + \frac{\rho_0^{-(\ell-2r+1)}}{\tau^r} + \tau^{r+1}\rho_0^{-(\ell+2)}\right],\end{aligned}$$

where $\rho_0^{-(\ell-2r+1)}$, $\rho_0^{-(\ell+2)}$ denote, respectively, $\rho_{[t_0,t]}^{-(\ell-2r+1)}(s)$, $\rho_{[t_0,t]}^{-(\ell+2)}(s)$. Depending on the sign of $\ell-2r+1$ and $t+\Re s$, the term $\rho_0^{-(\ell-2r+1)}$ has different estimates. Thus, for $(t,s)\in D_1$ and $t+\Re s<0$

$$\rho_0^{-(\ell+2)}\leq\tau^{-(\ell+2)},\quad \rho_0^{-(\ell-2r+1)}\leq\begin{cases}\tau^{-(\ell-2r+1)}, & \ell-2r+1>0\\ \left|\ln\tau\right|, & \ell-2r+1=0\\ K, & \ell-2r+1\leq 0\end{cases},$$

whereas for $(t,s)\in D_1$ and $t+\Re s\geq 0$

$$\rho_0^{-(\ell+2)}\leq\varepsilon^{-(\ell+2)},\quad \rho_0^{-(\ell-2r+1)}\leq\begin{cases}\varepsilon^{-(\ell-2r+1)}, & \ell-2r+1>0\\ \left|\ln\varepsilon\right|, & \ell-2r+1=0\\ K, & \ell-2r+1\leq 0\end{cases},$$

and $\tau^{2r+1}\leq\varepsilon^{r+1}$. Hence, in all the domain $D_1$ we have

$$\tau^{2r+1}\rho_0^{-(\ell+2)}\leq\frac{1}{\varepsilon^{\ell-r+1}},\qquad \rho_0^{-(\ell-2r+1)}\leq K\left(\frac{\left|\ln\varepsilon\right|}{\varepsilon^{\ell-2r+1}}\right). \tag{4.24}$$

Using these bounds above, jointly with the fact that $\ell\geq r-1$ (see remark *R3*), we obtain the following estimate for $\xi^1(t)$:

$$\begin{aligned}\left|\xi^1(t)-\mu\varepsilon^{p+1}G(x^0(t+s),t/\varepsilon)\right|_\tau\tau^r&\\ \leq K\mu\varepsilon^{p+2}&\left[1+\tau^{2r+1}+\frac{1}{\tau^{\ell-2r+1}}+\rho_0^{-(\ell-2r+1)}+\tau^{2r+1}\rho_0^{-(l+2)}\right]\\ \leq K\mu\varepsilon^{p+2}&\left[1+\frac{\left|\ln\varepsilon\right|}{\varepsilon^{\ell-2r+1}}+\frac{1}{\varepsilon^{\ell-r+1}}\right]\leq K\mu\varepsilon^{\gamma+r+1}.\end{aligned}$$

Introducing the norm

$$\left\|\xi\right\|_r:=\sup\left|\xi(t)\right|_\tau\tau^r,$$

where the supremum is taken on $t\in[t_0,t_1(s)]$, the estimate above for $\xi^1$ reads as

$$\left\|\xi^1-\mu\varepsilon^{p+1}G\right\|_r\leq K\mu\varepsilon^{\gamma+r+1}.$$

We now proceed by induction. Assuming that for $k=1,\ldots,n$,

$$\left\|\xi^k-\mu\varepsilon^{p+1}G\right\|_r\leq K\mu\varepsilon^{\gamma+r+1},$$

estimate (4.23) on $G$ gives

$$\left|\xi^k(t)\right|_\tau\leq\eta(\tau):=K\frac{\mu\varepsilon^{p+1}}{\tau^{\ell-r}}+K\frac{\mu\varepsilon^{\gamma+r+1}}{\tau^r}.$$

Since $\gamma = p - \ell \geq 0$ and $\varepsilon \leq \tau$ on $D_1$, we can bound $\eta(\tau)$ as $\eta(\tau) \leq K\mu\varepsilon^\gamma/\tau^{r-1}$, and hence we can apply estimate (4.15) to $F(\xi^n(t), t+s, t/\varepsilon) - F(\xi^{n-1}(t), t+s, t/\varepsilon)$:

$$\begin{aligned}\left|F(\xi^n(t), t+s, t/\varepsilon) - F(\xi^{n-1}(t), t+s, t/\varepsilon)\right|_\tau \\ &\leq K\mu\left(\frac{\varepsilon^p}{\tau^{\ell-2r+1}} + \frac{\varepsilon^{p+1}}{\tau^{\ell-2r+2}} + \frac{\varepsilon^{\gamma+r+1}}{\tau^2}\right)\left|\xi^n - \xi^{n-1}\right|_\tau \\ &\leq K\mu\left(\frac{\varepsilon^p}{\tau^{\ell-r+1}} + \frac{\varepsilon^{p+1}}{\tau^{\ell-r+2}} + \frac{\varepsilon^{\gamma+r+1}}{\tau^{r+2}}\right)\left\|\xi^n - \xi^{n-1}\right\|_r.\end{aligned}$$

Applying thrice Lemma 4.3 with $\beta = \ell - r + 1$ and $\mathrm{C} = \varepsilon^p$, $\beta = \ell - r + 2$ and $\mathrm{C} = \varepsilon^{p+1}$, $\beta = r + 2$ and $\mathrm{C} = \varepsilon^{\gamma+r+1}$, respectively, we obtain

$$\begin{aligned}&\left|M(t+s)\int_{t_0}^t M(\sigma+s)^{-1}\left(F(\xi^n(\sigma), \sigma+s, \sigma/\varepsilon) - F(\xi^{n-1}(\sigma), \sigma+s, \sigma/\varepsilon)\right)\mathrm{d}\sigma\right|_\tau \\ &\leq \left[K\mu\varepsilon^p\left(\frac{\rho_0^{-(\ell-2r)}}{\tau^r} + \tau^{r+1}\rho_0^{-(\ell+1)}\right) + K\mu\varepsilon^{p+1}\left(\frac{\rho_0^{-(\ell-2r+1)}}{\tau^r} + \tau^{r+1}\rho_0^{-(\ell+2)}\right)\right. \\ &\quad \left. + K\mu\varepsilon^{\gamma+r+1}\left(\frac{\rho_0^{-(1)}}{\tau^r} + \tau^{r+1}\rho_0^{-(2r+2)}\right)\right]\left\|\xi^n - \xi^{n-1}\right\|_r.\end{aligned}$$

Finally, multiplying by $\tau^r$ and taking supremum, and using inequalities like those of (4.24), we arrive at

$$\begin{aligned}\left\|\xi^{n+1} - \xi^n\right\|_r &\leq K\mu\left[\varepsilon^p\left(1 + \frac{|\ln\varepsilon|}{\varepsilon^{\ell-2r}} + \frac{1}{\varepsilon^{\ell-r}}\right) + \varepsilon^{p+1}\left(1 + \frac{|\ln\varepsilon|}{\varepsilon^{\ell-2r+1}} + \frac{1}{\varepsilon^{\ell-r+1}}\right)\right. \\ &\qquad \left. + \varepsilon^{\gamma+r+1}\left(\frac{1}{\varepsilon} + \frac{1}{\varepsilon^{r+1}}\right)\right]\left\|\xi^n - \xi^{n-1}\right\|_r \\ &\leq K\mu(\varepsilon^p + \varepsilon^\gamma)\left\|\xi^n - \xi^{n-1}\right\|_r.\end{aligned}$$

If we choose now $\mu_0$ small enough, and $\gamma \geq 0$, (and hence $p \geq 0$) it follows that for $n \geq 1$, $|\mu| \leq \mu_0$,

$$\begin{aligned}\left\|\xi^n - \mu\varepsilon^{p+1}G\right\|_r &\leq 2\left\|\xi^1 - \mu\varepsilon^{p+1}G\right\|_r \leq K\mu\varepsilon^{\gamma+r+1}, \\ \left\|\xi^{n+1} - \xi^n\right\|_r &\leq \frac{1}{2}\left\|\xi^n - \xi^{n-1}\right\|_r,\end{aligned}$$

and consequently $(\xi^n)_{n\geq 0}$ converges uniformly on $t \in [t_0, t_1(s)]$ to the solution $\xi(t)$ of system (4.2), satisfying there

$$\left\|\xi - \mu\varepsilon^{p+1}G\right\|_r \leq K\mu\varepsilon^{\gamma+r+1},$$

and hence estimate (4.20). Estimate (4.21) is then an easy consequence of estimate (4.23) on $G$ and the fact that $\varepsilon \leq \tau$ and $\ell \geq 0$:

$$|\xi(t)|_\tau \leq K\frac{\mu\varepsilon^{p+1}}{\tau^{\ell-r}} + K\frac{\mu\varepsilon^{\gamma+r+1}}{\tau^r} \leq K\frac{\mu\varepsilon^{p+1}\tau^r}{\varepsilon^\ell} + K\mu\varepsilon^{\gamma+1} \leq K\mu\varepsilon^{\gamma+1}.$$

□

## 4.6 Second domain

On the final point $t_1(s)$, estimate (4.20) provided by Proposition 4.4 reads as:

$$\left|\xi(t_1) - \mu\varepsilon^{p+1} G(x^0(t_1+s), t_1/\varepsilon)\right|_{\tau_1} \leq K\frac{\mu\varepsilon^{\gamma+1+r}}{\tau_1^r}, \tag{4.25}$$

were $\tau_1 = |t_1 + s - a\,\mathrm{i}|$.

**Proposition 4.5** *Given $s \in \mathbf{C}$ such that $0 \leq \Im s \leq a - \varepsilon$, let $\xi(t) = \xi(t,s)$ be a solution of system (4.2) with initial condition (4.25) on $t_1 = t_1(s)$ as given in (4.19). Then, if $\gamma := p - \ell \geq 0$, the solution $\xi(t)$ can be extended for $t \in [t_1(s), T - \Re s]$, satisfying there the following estimate:*

$$|\xi(t)|_\tau \leq K\mu\varepsilon^\gamma \tau^{r+1}. \tag{4.26}$$

*Proof.* We shall use exactly the same method of successive approximations as in Proposition 4.4, but replacing the initial condition $t_0$ by $t_1$:

$$\xi^{n+1}(t) = \xi^1(t) + M(t+s)\int_{t_1}^t M^{-1}(\sigma+s)F(\xi^n(\sigma), \sigma+s, \sigma/\varepsilon)\,\mathrm{d}\sigma,$$

for $t \in [t_1(s), T - \Re s]$. The first iterate is $\xi^1(t)$ as given by expression (4.10), but with $t_1$ instead of $t_0$.

From initial condition (4.25) and estimate (4.12), we can bound one term of the expression (4.10) of $\xi^1(t)$:

$$\left|M(t+s)M(t_1+s)^{-1}(\xi^1(t_1) - \mu\varepsilon^{p+1}G(x^0(t_1+s), t_1/\varepsilon))\right|_\tau \leq K\mu\varepsilon^{\gamma+r+1}\left(\frac{1}{\tau^r} + \frac{\tau^{r+1}}{\tau_1^{2r+1}}\right).$$

We use the expressions (4.22) of $m'$, $m''$, for the terms involving them. With the help of bounds (4.23), we apply (4.12) for the terms involving $m'$ in expression (4.10) of $\xi^1(t)$, and estimate (4.17) with $\beta = \ell - r + 2$ and $\mathrm{C} = \mu\varepsilon^{p+2}$ for the term involving $m''$ to get

$$\begin{aligned}\left|\xi^1 - \mu\varepsilon^{p+1}G\right|_\tau \;\leq\; & K\mu\varepsilon^{\gamma+r+1}\left(\frac{1}{\tau^r} + \frac{\tau^{r+1}}{\tau_1^{2r+1}}\right) + K\frac{\mu\varepsilon^{p+2}}{\tau^{\ell-r+1}} \\ & + K\frac{\mu\varepsilon^{p+2}}{\tau_1^{\ell-r+1}}\left(\frac{\tau_1^r}{\tau^r} + \frac{\tau^{r+1}}{\tau_1^{r+1}}\right) + K\mu\varepsilon^{p+2}\left(\frac{\rho_1^{-(\ell-2r+1)}}{\tau^r} + \tau^{r+1}\rho_1^{-(\ell+2)}\right),\end{aligned}$$

where $\rho_1^{-(\ell-2r+1)}$, $\rho_1^{-(\ell+2)}$ denote, respectively, $\rho_{[t_1,t]}^{-(\ell-2r+1)}(s)$, $\rho_{[t_1,t]}^{-(\ell+2)}(s)$. Now, for $(t,s) \in D_2$, these terms can be bounded as

$$\rho_1^\beta \leq \begin{cases} \tau^\beta, & \beta > 0 \\ |\ln\tau_1|, & \beta = 0 \\ \tau_1^\beta, & \beta < 0 \end{cases}, \tag{4.27}$$

and consequently, we obtain the following estimate for $\xi^1(t)$:

$$\begin{aligned}\frac{|\xi^1 - \mu\varepsilon^{p+1}G|_\tau}{\tau^{r+1}} &\leq K\mu\varepsilon^{\gamma+r+1}\left(\frac{1}{\tau^{2r+1}} + \frac{1}{\tau_1^{2r+1}}\right) + K\frac{\mu\varepsilon^{p+2}}{\tau^{\ell+2}} \\ &\quad + K\frac{\mu\varepsilon^{p+2}}{\tau_1^{\ell-r+1}}\left(\frac{\tau_1^r}{\tau^{2r+1}} + \frac{1}{\tau_1^{r+1}}\right) + K\mu\varepsilon^{p+2}\left(\frac{\rho_1^{-(\ell-2r+1)}}{\tau^{2r+1}} + \rho_1^{-(\ell+2)}\right) \\ &\leq K\mu\varepsilon^\gamma,\end{aligned}$$

where we have used that $\varepsilon < \varepsilon^q \leq \tau_1 \leq \tau$, and $q = (r+1)/(2r+1)$. Bound (4.23) on $G$, jointly with $\tau \geq \varepsilon$, gives at last

$$\left|\xi^1(t)\right|_\tau \tau^{-(r+1)} \leq K\mu\varepsilon^\gamma + K\frac{\mu\varepsilon^{p+1}}{\tau^{\ell+1}} \leq K\mu\varepsilon^\gamma.$$

In view of this bound, we define the norm

$$\|\xi\|_{-(r+1)} := \sup |\xi(t)|_\tau \tau^{-(r+1)},$$

where the supremum is taken on $t \in [t_1(s), T - \Re s]$. With this new terminology we have proved that

$$\left\|\xi^1\right\|_{-(r+1)} \leq K\mu\varepsilon^\gamma.$$

We now proceed by induction. Assuming that for $k = 1, \ldots, n$,

$$\left\|\xi^k\right\|_{-(r+1)} \leq K\mu\varepsilon^\gamma,$$

and consequently

$$\left|\xi^k(t)\right|_\tau \leq \eta(\tau) := K\mu\varepsilon^\gamma\tau^{r+1},$$

then obviously $\eta(\tau) \leq K\mu\varepsilon^\gamma/\tau^{r-1}$, and we apply estimate (4.15) to get

$$\begin{aligned}&\left|F\left(\xi^n(t), t+s, t/\varepsilon\right) - F\left(\xi^{n-1}(t), t+s, t/\varepsilon\right)\right|_\tau \\ &\quad \leq K\left(\frac{\mu\varepsilon^p}{\tau^{\ell-2r+1}} + \frac{\mu\varepsilon^\gamma\tau^{r+1}}{\tau^{2-r}}\right)\left|\xi^n - \xi^{n-1}\right|_\tau \\ &\quad \leq K\left(\frac{\mu\varepsilon^p}{\tau^{\ell-3r}} + \mu\varepsilon^\gamma\tau^{3r}\right)\left\|\xi^n - \xi^{n-1}\right\|_{-(r+1)} \leq K\mu\varepsilon^\gamma\tau^{3r}\left\|\xi^n - \xi^{n-1}\right\|_{-(r+1)}.\end{aligned}$$

Applying estimate (4.17) of Lemma 4.3 with $\beta = -3r$ and $\mathrm{C} = \mu\varepsilon^\gamma$, we obtain

$$\begin{aligned}&\left|M(t+s)\int_{t_1}^t M(\sigma+s)^{-1}\left(F(\xi^n(\sigma), \sigma+s, \sigma/\varepsilon) - F(\xi^{n-1}(\sigma), \sigma+s, \sigma/\varepsilon)\right)\mathrm{d}\sigma\right|_\tau \\ &\qquad\qquad \leq K\mu\varepsilon^\gamma\left(\frac{\rho_1^{4r+1}}{\tau^r} + \tau^{r+1}\rho_1^{2r}\right)\left\|\xi^n - \xi^{n-1}\right\|_{-(r+1)},\end{aligned}$$

and using inequalities (4.27), we arrive at

$$\begin{aligned}\left|\xi^{n+1}(t)-\xi^n(t)\right|_\tau \tau^{-(r+1)} &\le K\mu\varepsilon^\gamma\left(\frac{\rho_1^{4r+1}}{\tau^{2r+1}}+\rho_1^{2r}\right)\left\|\xi^n-\xi^{n-1}\right\|_{-(r+1)}\\ &\le K\mu\varepsilon^\gamma\left\|\xi^n-\xi^{n-1}\right\|_{-(r+1)}.\end{aligned}$$

Since $\gamma\ge 0$, choosing now $\mu_0$ small enough, it follows by induction that for $n\ge 1$, $|\mu|\le\mu_0$,

$$\begin{aligned}\left\|\xi^n\right\|_{-(r+1)} &\le K\mu\varepsilon^\gamma,\\ \left\|\xi^{n+1}-\xi^n\right\|_{-(r+1)} &\le \frac{1}{2}\left\|\xi^n-\xi^{n-1}\right\|_{-(r+1)},\end{aligned}$$

and thus $(\xi^n)_{n\ge 0}$ converges uniformly on $t\in[t_1(s),T-\Re s]$ to the solution $\xi(t)$ of system (4.2), satisfying there the required estimate (4.26). □

## 4.7 Proof of Theorem 2.4

First consider $0\le\Im s\le a-\varepsilon$. Putting Propositions 4.4 and 4.5 together, from $|\xi(t)|_\tau = |\xi_1(t)|+|\xi_2(t)|\,\tau$, we immediately obtain $\xi(t)=\mathrm{O}(\mu\varepsilon^\gamma)$, and the Extension Theorem 2.4 is proved.

For $-a+\varepsilon\le\Im s\le 0$ we only have to choose $b=-a\,\mathrm{i}$ in the definition of $W(u)$, in order to get a second solution $\Phi(u)$ of the linear system (4.5) having a zero of multiplicity $r+1$ at $u=-a\,\mathrm{i}$. Propositions 4.4 and 4.5 follow exactly in the same way for $-a+\varepsilon\le\Im s\le 0$, as well as the Extension Theorem. □

**Remark 4.6** The proof given here can be generalized for perturbations $h^1(x,\theta)$ not necessarily polynomials, but verifying (4.14). In this case, $\gamma$ has to be chosen as $\gamma=\min(p-r+1,p-\ell)$, and the condition $\gamma\ge 0$ is also required.

# 5 Proof of Propositions 2.6 and 2.7

## Proof of Proposition 2.6

1. Using (2.15) and (2.13) in the definition (2.20) of $\mathcal{E}^{\mathrm{u}}(s)$, it follows that

$$\mathcal{E}^{\mathrm{u}}(s)=\mathcal{E}(x^{\mathrm{u}}(t,s),t/\varepsilon)-\mathcal{E}(x^{\mathrm{s}}(t,s),t/\varepsilon)=h^0(x^{\mathrm{u}}(t,s))-h^0(x^{\mathrm{s}}(t,s))+\mathrm{O}(\mu\varepsilon^{p+1}),\quad(5.1)$$

for $t$ such that $T/2\le t+\Re s\le T$, in such a way that both manifolds $x^{\mathrm{u}}(t,s)$ and $x^{\mathrm{s}}(t,s)$ belong to $\mathcal{U}$. Since $\mathcal{E}^{\mathrm{u}}(s)$ does not depend on $t$, from now on we take for example $t=T_s/2$, with $T_s:=T-\Re s$.

For $*=\mathrm{s},\mathrm{u}$, let us introduce the functions

$$\Delta^*(t,s)=h^0\left(x^*(t,s)\right)-h^0\left(\gamma_p(t/\varepsilon)\right).$$

It is straightforward to check that:

$$\begin{aligned}
\lim_{t\to+\infty}\Delta^{\mathrm{s}}(t,s)=0, \qquad & \lim_{t\to-\infty}\Delta^{\mathrm{u}}(t,s)=0,\\
\partial_t\Delta^*(t,s) &= \mu\varepsilon^p\left(\{h^0,h^1\}\left(x^*(t,s),t/\varepsilon\right)-\{h^0,h^1\}\left(\gamma_p(t/\varepsilon),t/\varepsilon\right)\right),\\
h^0\left(x^{\mathrm{u}}(t,s)\right)-h^0\left(x^{\mathrm{s}}(t,s)\right) &= \Delta^{\mathrm{u}}(t,s)-\Delta^{\mathrm{s}}(t,s),
\end{aligned}$$

and thus

$$\begin{aligned}
h^0\left(x^{\mathrm{u}}(T_s/2,s)\right)-h^0\left(x^{\mathrm{s}}(T_s/2,s)\right)=\mu\varepsilon^p\Bigg[&\int_{-\infty}^{T_s/2}\left(\{h^0,h^1\}(x^{\mathrm{u}},t/\varepsilon)-\{h^0,h^1\}(\gamma_p,t/\varepsilon)\right)\mathrm{d}t\\
&+\int_{T_s/2}^{\infty}\left(\{h^0,h^1\}(x^{\mathrm{s}},t/\varepsilon)-\{h^0,h^1\}(\gamma_p,t/\varepsilon)\right)\mathrm{d}t\Bigg],
\end{aligned}$$

where $x^{\mathrm{u}}$, $x^{\mathrm{s}}$ and $\gamma_p$ denote, respectively, $x^{\mathrm{u}}(t,s)$, $x^{\mathrm{s}}(t,s)$ and $\gamma_p(t/\varepsilon)$. Adding and subtracting the Melnikov integral, we get:

$$\begin{aligned}
&h^0(x^{\mathrm{u}}(T_s/2,s))-h^0(x^{\mathrm{s}}(T_s/2,s))\\
&\quad=\ \mu\varepsilon^p\Bigg[\int_{-\infty}^{-T_s/2}\left(\{h^0,h^1\}(x^{\mathrm{u}},t/\varepsilon)-\{h^0,h^1\}(\gamma_p,t/\varepsilon)-\{h^0,h^1\}(x^0,t/\varepsilon)\right)\mathrm{d}t\\
&\qquad+\int_{-T_s/2}^{T_s/2}\left(\{h^0,h^1\}(x^{\mathrm{u}},t/\varepsilon)-\{h^0,h^1\}(\gamma_p,t/\varepsilon)-\{h^0,h^1\}(x^0,t/\varepsilon)\right)\mathrm{d}t\\
&\qquad+\int_{T_s/2}^{+\infty}\left(\{h^0,h^1\}(x^{\mathrm{s}},t/\varepsilon)-\{h^0,h^1\}(\gamma_p,t/\varepsilon)-\{h^0,h^1\}(x^0,t/\varepsilon)\right)\mathrm{d}t\\
&\qquad+\int_{-\infty}^{+\infty}\{h^0,h^1\}(x^0,t/\varepsilon)\,\mathrm{d}t\Bigg],
\end{aligned}$$

where $x^0$ denotes $x^0(t+s)$ inside the four integrals in this expression. The last one is the Melnikov function (1.4) and we have to bound the other three integrals. The first and the third ones are $\mathrm{O}(\mu\varepsilon^{p+1})$ by (2.10). For the second one we need the following lemma:

**Lemma 5.1** *For $s\in\mathbf{C}$, $|\Im s|\le a-\varepsilon$ and $T_s:=T-\Re s$,*

$$\int_{-T_s/2}^{T_s/2}\left|\{h^0,h^1\}(x^{\mathrm{u}},t/\varepsilon)-\{h^0,h^1\}(\gamma_p,t/\varepsilon)-\{h^0,h^1\}(x^0,t/\varepsilon)\right|\mathrm{d}t\le K\mu\varepsilon^{\gamma-\ell+r-1},$$

*where $x^{\mathrm{u}}$, $x^0$ and $\gamma_p$ denote, respectively, $x^{\mathrm{u}}(t,s)$, $x^0(t+s)$ and $\gamma_p(t/\varepsilon)$.*

*Proof.* Since $\{h^0,h^1\}(x,t/\varepsilon)=-f(x_1)\partial_2h^1(x,t/\varepsilon)-x_2\partial_1h^1(x,t/\varepsilon)$, we can write

$$\begin{aligned}
&\{h^0,h^1\}(x^{\mathrm{u}},t/\varepsilon)-\{h^0,h^1\}(x^0,t/\varepsilon)\\
&\quad=\ -f(x_1^{\mathrm{u}})\left(\partial_2h^1(x^{\mathrm{u}},t/\varepsilon)-\partial_2h^1(x^0,t/\varepsilon)\right)-\left(f(x_1^{\mathrm{u}})-f(x_1^0)\right)\partial_2h^1(x^0,t/\varepsilon)\\
&\qquad-x_2^{\mathrm{u}}\left(\partial_1h^1(x^{\mathrm{u}},t/\varepsilon)-\partial_1h^1(x^0,t/\varepsilon)\right)-\left(x_2^{\mathrm{u}}-x_2^0\right)\partial_1h^1(x^0,t/\varepsilon).
\end{aligned}$$

With the help of bounds (4.13), (4.14) and Lemma 4.2, we now proceed to estimate this expression. Using also the bound $|\xi(t)|_\tau \le K\mu\varepsilon^\gamma$, which comes from the estimate $\xi := x^{\rm u} - x^0 = {\rm O}(\mu\varepsilon^\gamma)$, we get

$$\begin{aligned}
&\Big|\{h^0,h^1\}(x^{\rm u}(t,s),t/\varepsilon) - \{h^0,h^1\}(x^0(t+s),t/\varepsilon)\Big| \\
&\qquad \le \left(\frac{K}{\tau^{r+1}} + \frac{\mu\varepsilon^\gamma}{\tau^2}\right)\frac{\mu\varepsilon^\gamma}{\tau^{\ell-2r+1}} + \frac{\mu\varepsilon^\gamma}{\tau^2}\frac{K}{\tau^{\ell-r}} + \left(\frac{K}{\tau^r} + \mu\varepsilon^\gamma\right)\frac{\mu\varepsilon^\gamma}{\tau^{\ell-2r+2}} + \mu\varepsilon^\gamma\frac{K}{\tau^{\ell-r+1}} \\
&\qquad \le K\frac{\mu\varepsilon^\gamma}{\tau^{\ell-r+2}}.
\end{aligned}$$

Applying (4.16) with $\beta = \ell - r + 2$, it turns out that the integral of the expression above is ${\rm O}(\mu\varepsilon^{\gamma-\ell+r-1})$. The integral involving $\gamma_p$ is ${\rm O}(\mu\varepsilon^{p+1})$, as $\gamma_p = {\rm O}(\mu\varepsilon^{p+1})$ (see the Normal Form Theorem), and $f(0) = 0$, hence $\{h^0,h^1\}(\gamma_p,t/\varepsilon) = {\rm O}(\mu\varepsilon^{p+1})$, and the same will happen to its integral over $[-T_s/2, T_s/2]$. □

Collecting the bounds for the three integrals, we obtain

$$h^0(x^{\rm u}(T_s/2,s)) - h^0(x^{\rm s}(T_s/2,s)) = \mu\varepsilon^p M(s,\varepsilon) + {\rm O}(\mu\varepsilon^p\mu\varepsilon^{\gamma-\ell+r-1}, \mu^2\varepsilon^{2p+1}),$$

and thus (2.21) follows from (5.1).

2. To take advantage of estimate (2.21) on complex values of $s$, we simply estimate the Fourier coefficients $\mathcal{E}^{\rm u}_k$ of $\mathcal{E}^{\rm u}(s) = \sum_k \mathcal{E}^{\rm u}_k\,{\rm e}^{{\rm i}ks/\varepsilon}$, for $k \neq 0$, shifting along complex lines $\Im u = \pm r_\varepsilon$, with $r_\varepsilon = a - \varepsilon$:

$$\mathcal{E}^{\rm u}_k = \frac{{\rm e}^{-|k|r_\varepsilon/\varepsilon}}{2\pi\varepsilon}\int_0^{2\pi\varepsilon} \mathcal{E}^{\rm u}(\sigma \pm {\rm i}r_\varepsilon)\,{\rm e}^{{\rm i}k\sigma/\varepsilon}\,{\rm d}\sigma = \mu\varepsilon^p M_k(\varepsilon) + {\rm O}(\mu^2\varepsilon^{2\gamma+r-1}, \mu\varepsilon^{p+1})\,{\rm e}^{-|k|a/\varepsilon},$$

where $M_k(\varepsilon)$ are the Fourier coefficients of the Melnikov function. Now, estimate (2.22) follows readily.

3. We recall that $\mathcal{S}^{\rm u}(s) - s$ is a $2\pi\varepsilon$-periodic, analytic function, defined on $|\Im s| \le a - \varepsilon$ by $\mathcal{S}^{\rm u}(s) - s = \mathcal{S}(x^{\rm u}(t,s),t/\varepsilon) - t - s$, for any $t \in \mathbf{R}$ such that $T/2 \le t + \Re s \le T$. By (2.13), $\mathcal{S}$ is ${\rm O}(\mu\varepsilon^{p+1})$-close to $\mathcal{S}^0$, which in its turn satisfies $\mathcal{S}^0(x^0(t+s)) = t + s$ as an special case of (2.15). Using also the estimate (2.18) provided by the Extension Theorem, we arrive at

$$\begin{aligned}
\mathcal{S}^{\rm u}(s) - s &= \mathcal{S}(x^{\rm u}(t,s),t/\varepsilon) - t - s = \mathcal{S}^0(x^{\rm u}(t,s)) - t - s + {\rm O}(\mu\varepsilon^{p+1}) \\
&= \mathcal{S}^0(x^0(t+s)) - t - s + {\rm O}(\mu\varepsilon^\gamma, \mu\varepsilon^{p+1}) = {\rm O}(\mu\varepsilon^\gamma),
\end{aligned}$$

for $|\Im s| \le a - \varepsilon$. Estimating now the Fourier coefficients of $\mathcal{S}^{\rm u}(s) - s$ and also those of its derivative (which has zero mean), we get, for real values of $s$,

$$\begin{aligned}
\mathcal{S}^{\rm u}(s) - s &= \mathcal{S}^{\rm u}_0 + {\rm O}(\mu\varepsilon^\gamma)\,{\rm e}^{-a/\varepsilon}, \\
\frac{{\rm d}\mathcal{S}^{\rm u}}{{\rm d}s}(s) - 1 &= {\rm O}(\mu\varepsilon^{\gamma-1})\,{\rm e}^{-a/\varepsilon},
\end{aligned} \tag{5.2}$$

and therefore $\mathcal{S}^{\mathrm{u}}(s)$ can be inverted for real $s$. (In fact, it can also be inverted for $|\Im s| \leq a - \varepsilon\,|\ln \varepsilon|$.)

For real $s$, we can bound $\mathcal{S}^{\mathrm{u}}(s) - s$ repeating the computations above, but using estimate (2.19) provided by the real version of the Extension Theorem, instead of (2.18). This gives

$$\mathcal{S}^{\mathrm{u}}(s) = s + \mathrm{O}(\mu\varepsilon^{p+1}), \tag{5.3}$$

and in particular $\mathcal{S}^{\mathrm{u}}_0 = \mathrm{O}(\mu\varepsilon^{p+1})$ for the zero order Fourier coefficient $\mathcal{S}^{\mathrm{u}}_0$ of $\mathcal{S}^{\mathrm{u}}(s) - s$ that appears in formula (5.3).

Using formulae (5.2) and (5.3), we obtain for the inverse function $s = s^{\mathrm{u}}(S)$ of $S = \mathcal{S}^{\mathrm{u}}(s)$ that $s^{\mathrm{u}}(S) - S$ is $\mathrm{O}(\mu\varepsilon^{p+1})$ and a $2\pi\varepsilon$-periodic, analytic function. □

## Proof of Proposition 2.7

It is clear that $\psi$ is an analytic and periodic function because so are $\mathcal{E}^{\mathrm{u}}$ and $\mathcal{S}^{\mathrm{u}} - s$ given in (2.20).

1. For real $s$, according to property (2) of Corollary 2.2, the invariant stable and unstable curves $C^*$, $* = \mathrm{s}, \mathrm{u}$ for the Poincaré map $P$ defined in (1.3) are given by $C^* = \{x^*(0, s)\}$, and the dynamics on them is simply given by a shift in the variable $s$: $P(x^*(0, s)) = x^*(2\pi\varepsilon, s) = x^*(0, s + 2\pi\varepsilon)$. Since the Poincaré map $P$ is area preserving, $C^{\mathrm{s}}$ and $C^{\mathrm{u}}$ must intersect at least in a homoclinic point $x^h = x^{\mathrm{u}}(0, h^{\mathrm{u}}) = x^{\mathrm{s}}(0, h^{\mathrm{s}})$, giving rise to a homoclinic orbit: $x^{\mathrm{u}}(t, h^{\mathrm{u}}) = x^{\mathrm{s}}(t, h^{\mathrm{s}})$, $\forall t \in \mathbf{R}$. To see that $h^{\mathrm{s}} = \mathcal{S}^{\mathrm{u}}(h^{\mathrm{u}})$, we take $t$ big enough ($t + s \geq T/2$) in such a way that $x^{\mathrm{s}}(t, h^{\mathrm{s}}) \in D^{\mathrm{s}}$, and then equations (2.15) for $s = h^{\mathrm{s}}$ read as

$$\mathcal{S}(x^{\mathrm{s}}(t, h^{\mathrm{s}}), t/\varepsilon) - t = h^{\mathrm{s}}, \qquad \mathcal{E}(x^{\mathrm{s}}(t, h^{\mathrm{s}}), t/\varepsilon) = 0, \tag{5.4}$$

and from the first equality above and definition (2.20) of $\mathcal{S}^{\mathrm{u}}$, we get

$$h^{\mathrm{s}} = \mathcal{S}(x^{\mathrm{s}}(t, h^{\mathrm{s}}), t/\varepsilon) - t = \mathcal{S}(x^{\mathrm{u}}(t, h^{\mathrm{u}}), t/\varepsilon) - t = \mathcal{S}^{\mathrm{u}}(h^{\mathrm{u}}),$$

as wanted. Now, from the definition (2.23) of $\psi$, as well as (2.20) and (5.4),

$$\psi(h^{\mathrm{s}}) = \psi(\mathcal{S}^{\mathrm{u}}(h^{\mathrm{u}})) = \mathcal{E}^{\mathrm{u}}(h^{\mathrm{u}}) = \mathcal{E}(x^{\mathrm{u}}(t, h^{\mathrm{u}}), t/\varepsilon) = \mathcal{E}(x^{\mathrm{s}}(t, h^{\mathrm{s}}), t/\varepsilon) = 0,$$

and by the $2\pi\varepsilon$-periodicity of $\psi$, $\psi(h_n) = 0$ also holds.

To compute $\psi'(h_n) = \psi'(h^{\mathrm{s}})$ we differentiate (2.24) at the point $h^{\mathrm{s}}$, obtaining

$$\psi'(h^{\mathrm{s}}) = \partial_1\mathcal{E}(\tilde{x}^{\mathrm{u}}(t, h^{\mathrm{s}}), t/\varepsilon) \cdot \frac{\partial \tilde{x}^{\mathrm{u}}_1}{\partial S}(t, h^{\mathrm{s}}) + \partial_2\mathcal{E}(\tilde{x}^{\mathrm{u}}(t, h^{\mathrm{s}}), t/\varepsilon) \cdot \frac{\partial \tilde{x}^{\mathrm{u}}_2}{\partial S}(t, h^{\mathrm{s}}).$$

Finally, differentiating both equations (2.15) with respect to $s = S$, and taking into account that change (2.11) is canonical we get

$$\begin{aligned}
\frac{\partial x^{\mathrm{s}}_1}{\partial S}(t, h^{\mathrm{s}}) &= \partial_2\mathcal{E}(x^{\mathrm{s}}(t, h^{\mathrm{s}}), t/\varepsilon) = \partial_2\mathcal{E}(\tilde{x}^{\mathrm{u}}(t, h^{\mathrm{s}}), t/\varepsilon), \\
\frac{\partial x^{\mathrm{s}}_2}{\partial S}(t, h^{\mathrm{s}}) &= -\partial_1\mathcal{E}(x^{\mathrm{s}}(t, h^{\mathrm{s}}), t/\varepsilon) = -\partial_1\mathcal{E}(\tilde{x}^{\mathrm{u}}(t, h^{\mathrm{s}}), t/\varepsilon),
\end{aligned}$$

and inserting these equalities in the formula of $\psi'(h_n)$, we get the required expression:

$$\psi'(h_n) = -\frac{\partial x_2^{\mathrm{s}}}{\partial S}(t, h^{\mathrm{s}}) \cdot \frac{\partial \tilde{x}_1^{\mathrm{u}}}{\partial S}(t, h^{\mathrm{s}}) + \frac{\partial x_1^{\mathrm{s}}}{\partial S}(t, h^{\mathrm{s}}) \cdot \frac{\partial \tilde{x}_2^{\mathrm{u}}}{\partial S}(t, h^{\mathrm{s}}). \tag{5.5}$$

Since the formula above for $\psi'(h_n)$ is independent of $n$, it can be used to compute the angle at any homoclinic point $x^{\mathrm{s}}(0, h_n) = x^{\mathrm{s}}(2\pi\varepsilon n, h^{\mathrm{s}})$.

2. The points $x^h = x^{\mathrm{s}}(0, h^{\mathrm{s}})$ and $P(x^h) = x^{\mathrm{s}}(0, h^{\mathrm{s}} + 2\pi\varepsilon)$ are homoclinic points of $P$, but since $P$ is orientation preserving there is another first homoclinic point between them: $x^{\mathrm{s}}(0, \bar{h}^{\mathrm{s}}) = x^{\mathrm{u}}(0, \bar{h}^{\mathrm{u}}) = \tilde{x}^{\mathrm{u}}(0, \bar{h}^{\mathrm{s}})$, where $h^{\mathrm{s}}$ and $\bar{h}^{\mathrm{s}}$ are two consecutive zeros of $\psi(S)$.

Since $P$ is area preserving, the area $A$ of the lobe $D$ in coordinates $x$ is the same as the area of the lobe $D'$ in coordinates $(S, E)$, and can be computed at any image of the homoclinic points, giving rise to the desired formula

$$A = \iint_{D'} \mathrm{d}S\,\mathrm{d}E = \left| \int_{h^{\mathrm{s}}}^{\bar{h}^{\mathrm{s}}} \psi(S)\,\mathrm{d}S \right|.$$

3. In order to see that $\psi_0 = 0$, we only need to check that the area of the inner lobes and the outer lobes is the same. This can be easily seen making one iterate of the map $P$ and using the fact that the total area between the global invariant manifolds is invariant.

4. By the definition of $\psi$, and applying (2.22), we have for real $S$

$$\psi(S) = \mathcal{E}_0^{\mathrm{u}} + \mu\varepsilon^p M(s^{\mathrm{u}}(S), \varepsilon) + \mathrm{O}(\mu^2\varepsilon^{2\gamma+r-1}, \mu\varepsilon^{p+1})\,\mathrm{e}^{-a/\varepsilon}.$$

An straightforward computation of the Melnikov function shows that

$$\mu\varepsilon^p M'(S, \varepsilon) = \mathrm{O}(\mu\varepsilon^{\gamma-1}\,\mathrm{e}^{-a/\varepsilon}), \tag{5.6}$$

for real $S$. Applying Taylor's Theorem to $\mu\varepsilon^p M(s^{\mathrm{u}}(S), \varepsilon) = \mu\varepsilon^p M(S + \mathrm{O}(\mu\varepsilon^{p+1}), \varepsilon)$, we get

$$\begin{aligned} \mu\varepsilon^p M(s^{\mathrm{u}}(S), \varepsilon) &= \mu\varepsilon^p M(S, \varepsilon) + \mathrm{O}(\mu\varepsilon^{\gamma-1}\,\mathrm{e}^{-a/\varepsilon}\mu\varepsilon^{p+1}) \\ &= \mu\varepsilon^p M(S, \varepsilon) + \mathrm{O}(\mu^2\varepsilon^{\gamma+p})\,\mathrm{e}^{-a/\varepsilon}, \end{aligned}$$

and then, since $\ell \geq r - 1$, we have that $\gamma + p \geq 2\gamma + r - 1$, and

$$\psi(S) = \mathcal{E}_0^{\mathrm{u}} + \mu\varepsilon^p M(S, \varepsilon) + \mathrm{O}(\mu^2\varepsilon^{2\gamma+r-1}, \mu\varepsilon^{p+1})\,\mathrm{e}^{-a/\varepsilon}.$$

Now, since $\psi_0 = 0$, we obtain that $\mathcal{E}_0^{\mathrm{u}} = \mathrm{O}(\mu^2\varepsilon^{2\gamma+r-1}, \mu\varepsilon^{p+1})\,\mathrm{e}^{-a/\varepsilon}$, which gives equation (2.25).

To check estimate (5.6), we simply apply residues theory to compute the Fourier coefficients $M_n(\varepsilon)$ of the Melnikov function $M(s, \varepsilon) = \sum_{n\neq 0} M_n(\varepsilon)\,\mathrm{e}^{\mathrm{i}nt/\varepsilon}$ defined in (1.4) in terms of the Poisson bracket $J(x, t/\varepsilon) = \{h^0, h^1\}(x, t/\varepsilon)$, which is a $2\pi\varepsilon$-periodic in

$t$ function with zero mean. We now relate its Fourier series in the $\theta$ variable $J(x,\theta) = \sum_{n\neq 0} J_n(x)\,\mathrm{e}^{\mathrm{i}n\theta}$, with the Fourier series of the Melnikov function

$$\begin{aligned}\mu\varepsilon^p M(s,\varepsilon) &= \mu\varepsilon^p \int_{-\infty}^{\infty} J(x^0(t+s),t/\varepsilon)\,\mathrm{d}t = \mu\varepsilon^p \int_{-\infty}^{\infty} J\left(x^0(u),\frac{u-s}{\varepsilon}\right)\mathrm{d}u \\ &= \mu\varepsilon^p \sum_{n\neq 0} \mathrm{e}^{-\mathrm{i}ns/\varepsilon} \int_{-\infty}^{\infty} J_n(x^0(u))\,\mathrm{e}^{\mathrm{i}nu/\varepsilon}\,\mathrm{d}u = \mu\varepsilon^p \sum_{n\neq 0} \mathrm{e}^{-\mathrm{i}ns/\varepsilon} M_{-n}(\varepsilon),\end{aligned}$$

obtaining thus $M_n(\varepsilon) = \int_{-\infty}^{\infty} J_{-n}(x^0(u))\,\mathrm{e}^{-\mathrm{i}nu/\varepsilon}\,\mathrm{d}u$.

Let us recall here that by hypothesis *H2*, $x^0(u)$ is analytic on the strip $|\Im u| < a$, with only one isolated singularity on each line $\Im u = \pm a$. To compute $M_n$ we change the integration path down to $\Im u = -b$, if $n > 0$, and up to $\Im u = b$, if $n < 0$; with $b > a$ such that $x^0(u)$ has no more singularities on $|\Im u| < b$. Then, taking into account that $u \mapsto J(x^0(u),\theta)$ has a pole of order $\leq \ell+1$ at $u = \pm a\mathrm{i}$, it follows that $J_n(x^0(u))$ has at most a pole of this order at $u = \pm a\mathrm{i}$, i.e., its Laurent series has the form $J_n(x^0(u)) = \sum_{k\leq \ell+1} J_{n,k}(u - a\,\mathrm{i})^{-k}$. Applying residues theory, we obtain

$$\mu\varepsilon^p M_n + \mathrm{O}(\,\mathrm{e}^{-nb/\varepsilon}) = \mu\varepsilon^{p-\ell}\,\mathrm{e}^{-na/\varepsilon}[(-\mathrm{i}n)^\ell J_{-n,\ell+1} + \mathrm{O}(\varepsilon)],$$

for instance for $n > 0$. The $\mathrm{O}(\,\mathrm{e}^{-nb/\varepsilon})$ term comes from the integral through the path parallel to the real axis, with $\Im u = -b < -a$. We can conclude that, for $n > 0$,

$$\begin{aligned}\mu\varepsilon^p M_n &= \mu\varepsilon^\gamma\,\mathrm{e}^{-na/\varepsilon}\left[(-\mathrm{i}n)^\ell J_{-n,\ell+1} + \mathrm{O}(\varepsilon)\right] \\ &= \mu\varepsilon^\gamma\,\mathrm{e}^{-na/\varepsilon}\tilde{M}_n, \qquad (5.7)\end{aligned}$$

and an analogous formula for $n < 0$

$$\begin{aligned}\mu\varepsilon^p M_n &= \mu\varepsilon^\gamma\,\mathrm{e}^{-na/\varepsilon}\left[(-\mathrm{i}n)^\ell J_{-n,\ell+1} + \mathrm{O}(\varepsilon)\right] \\ &= \mu\varepsilon^\gamma\,\mathrm{e}^{-na/\varepsilon}\tilde{M}_n, \qquad (5.8)\end{aligned}$$

with $\tilde{M}_n = \mathrm{O}(1)$. In conclusion, from formulae (5.7), (5.8), we obtain $\mu\varepsilon^p M_k(\varepsilon) = \mathrm{O}(\mu\varepsilon^\gamma\,\mathrm{e}^{-|k|a/\varepsilon})$, and thus estimate (5.6) follows. □

## Proof of Corollary 1.2

First of all, formulae (5.8), and (5.7), give us

$$\begin{aligned}\mu\varepsilon^p M(s,\varepsilon) &= \mu\varepsilon^\gamma \sum_{n>0} \mathrm{e}^{-na/\varepsilon}\left(\tilde{M}_{-n}\,\mathrm{e}^{-\mathrm{i}ns/\varepsilon} + \tilde{M}_n\,\mathrm{e}^{\mathrm{i}ns/\varepsilon}\right) \\ &= \mu\varepsilon^p\,\mathrm{e}^{-a/\varepsilon}\left[\tilde{M}_{-1}(\varepsilon)\,\mathrm{e}^{-\mathrm{i}s/\varepsilon} + \tilde{M}_1(\varepsilon)\,\mathrm{e}^{\mathrm{i}s/\varepsilon}\right] + \mathrm{O}(\,\mathrm{e}^{-2a/\varepsilon}) \\ &= \mu\varepsilon^p\left[M_{-1}(\varepsilon)\,\mathrm{e}^{-\mathrm{i}s/\varepsilon} + M_1(\varepsilon)\,\mathrm{e}^{\mathrm{i}s/\varepsilon}\right] + \mathrm{O}(\,\mathrm{e}^{-2a/\varepsilon}),\end{aligned}$$

and it only remains to check $\mu\varepsilon^p M_{\pm 1} \sim \mu\varepsilon^\gamma\,\mathrm{e}^{-a/\varepsilon}$. Again from formulae (5.7) and (5.8) for $n = \pm 1$, we get

$$\mu\varepsilon^p\left[M_{-1}\,\mathrm{e}^{-\mathrm{i}s/\varepsilon} + M_1\,\mathrm{e}^{\mathrm{i}s/\varepsilon}\right] = \mu\varepsilon^\gamma\,\mathrm{e}^{-a/\varepsilon}\left(\mathrm{i}^\ell J_{1,\ell+1}\,\mathrm{e}^{-\mathrm{i}s/\varepsilon} + (-\mathrm{i})^\ell J_{-1,\ell+1}\,\mathrm{e}^{+\mathrm{i}s/\varepsilon} + \mathrm{O}(\varepsilon))\right).$$

From hypothesis *H4*, we know that $J_{1,\ell+1} = \overline{J_{-1,\ell+1}}$ are not zero. Writing $J_{1,\ell+1} = |J_{1,\ell+1}|\ \mathrm{e}^{\mathrm{i}\varphi}$, $J_{-1,\ell+1} = |J_{1,\ell+1}|\ \mathrm{e}^{-\mathrm{i}\varphi}$, with $|J_{1,\ell+1}| > 0$, we obtain that

$$\mu\varepsilon^p M(s,\varepsilon) = 2\,|J_{1,\ell+1}|\,(-1)^\ell \mu\varepsilon^\gamma\,\mathrm{e}^{-a/\varepsilon}\cos(s/\varepsilon - \varphi) + \mathrm{O}(\,\mathrm{e}^{-2a/\varepsilon}),$$

and putting this expression into the formulae of the area and the angle given by Theorem 1.1 we obtain the desired result. □
