Objective. To develop a model to predict the structure and flexibility of standard, B-form DNA from its sequence.

Objective. To develop a model to predict the structure and flexibility of standard, B-form DNA from its sequence.

Idealized structure proposed by Watson and Crick, 1953.

Objective. To develop a model to predict the structure and flexibility of standard, B-form DNA from its sequence.

Idealized structure proposed by Watson and Crick, 1953.

Actual structure depends strongly on sequence, circa 1980.

Objective. To develop a model to predict the structure and flexibility of standard, B-form DNA from its sequence.

Idealized structure proposed by Watson and Crick, 1953.

Actual structure depends strongly on sequence, circa 1980.

Background. 30 years of history; lack of data hindered progress; recent construction of large MD dataset is making it accessible.

MD dataset. (consortium+local)

- over 50 different DNA oligomers (12-18 bp each)
- all 136 unique tetramer sub-sequences represented
- all 10 unique dimer end-sequences represented
- \bullet standard simulation protocol w/AMBER program
- \bullet all simulations w/explicit water and counterions
- 50-200 ns simulation time for each oligomer

Basic problem

Under fixed solvent conditions, we seek a model to predict the ground-state structure and flexibility of any given DNA oligomer.

w

$$\rho(w) = \frac{1}{Z} e^{-\beta U(w)}$$

configuration coordinates $\rho(w)$ probability density function U(w) free energy Ζ, β constants

▲ロト ▲帰ト ▲ヨト ▲ヨト 三日 - の々ぐ

Rigid-base representation

We consider a model in which each base is modeled as a separate rigid body; side-chains are not considered explicitly.

Configuration coordinates

An oligomer with *n* basepairs has 6n intra-basepair and 6(n-1) inter-basepair degrees of freedom; a total of N = 12n - 6.

The oligomer coord vector is $w = (y_1, z_1, \dots, z_{n-1}, y_n) \in \mathbb{R}^N$.

Free energy

Motivated by observed data, we consider a model in which the free energy is quadratic.

We seek explicit approximations to the functions $\mu(S)$ and K(S).

A monomer/dimer based model

We consider a model based on two types of interaction energies.

monomer interaction energy

$$\begin{array}{c} X \\ w_m = y \in \mathbb{R}^6 \end{array}$$

$$U_m = \frac{1}{2} (w_m - \mu_m^X) \cdot K_m^X (w_m - \mu_m^X)$$
$$\mu_m^X \in \mathbb{R}^6, \quad K_m^X \ge 0 \in \mathbb{R}^{6 \times 6}$$
$$X \in \{T, A, C, G\}$$

dimer interaction energy

$$\begin{aligned} U_d &= \frac{1}{2} (w_d - \mu_d^{XY}) \cdot K_d^{XY} (w_d - \mu_d^{XY}) \\ \mu_d^{XY} &\in \mathbb{R}^{18}, \quad K_d^{XY} \geq 0 \in \mathbb{R}^{18 \times 18} \\ X, Y &\in \{T, A, C, G\} \end{aligned}$$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへで

A monomer/dimer based model

By summing the monomer/dimer contributions along an oligomer, we obtain the energy

$$egin{aligned} U(w) &= rac{1}{2}(w-\mu)\cdot K(w-\mu) + C\ \mu &= \mu(S, \mathcal{P}), & K &= K(S, \mathcal{P}), \end{aligned} egin{aligned} C &= C(S, \mathcal{P}), \end{aligned}$$

where S is the oligomer sequence and \mathcal{P} is the model parameter set

$$\mathcal{P} = \begin{cases} \mathcal{K}_m^X, & \sigma_m^X := \mathcal{K}_m^X \mu_m^X, & X \in \{T, A, C, G\} \\ \\ \mathcal{K}_d^{XY}, & \sigma_d^{XY} := \mathcal{K}_d^{XY} \mu_d^{XY}, & X, Y \in \{T, A, C, G\} \end{cases}$$

A monomer/dimer based model

The ground-state configuration $\mu(S, \mathcal{P})$ and stiffness $K(S, \mathcal{P})$ are determined by $S = X_1 X_2 \cdots X_n$ and $\mathcal{P} = \{K_m^X, \sigma_m^X, K_d^{XY}, \sigma_d^{XY}\}.$

 $\mu: \qquad \qquad \mu(S, \mathcal{P}) = K(S, \mathcal{P})^{-1} \sigma(S, \mathcal{P})$

▲□▶ ▲□▶ ▲三▶ ▲三▶ 三三 のへで

Data for parameter estimation

To estimate the parameter set \mathcal{P} , we used a database of MD-observed probability densities $\rho_o^{(j)}(w)$ for sequences $S^{(j)}$, $j = 1, \ldots, J$.

$$\rho_{o}^{(j)}(w) = \frac{1}{Z^{(j)}} e^{-\beta U_{o}^{(j)}(w)}$$

$$U_o^{(j)}(w) = \frac{1}{2}(w - \mu_o^{(j)}) \cdot K_o^{(j)}(w - \mu_o^{(j)})$$

Functional for parameter estimation

A best-fit parameter set $\ensuremath{\mathcal{P}}$ can be obtained by minimizing the objective functional

$$\mathcal{F}(\mathcal{P}) = \sum_{j=1}^{J} D(\rho(S^{(j)}, \mathcal{P}), \rho_o^{(j)}),$$

where D is the Kullback-Leibler divergence (pre-distance)

$$D(
ho_*,
ho_{
m o})=\int
ho_*(w)\ln\left[rac{
ho_*(w)}{
ho_{
m o}(w)}
ight]\;dw.$$

For Gaussians,

$$D(\rho_*,\rho_{\rm o}) = \frac{1}{2} \left[K_*^{-1} : K_{\rm o} + (\mu_* - \mu_{\rm o}) \cdot K_{\rm o}(\mu_* - \mu_{\rm o}) - \ln\left(\frac{\det K_{\rm o}}{\det K_*}\right) - I : I \right]$$

Results

A best-fit parameter set ${\mathcal P}$ was obtained from the MD dataset via numerical minimization of the Kullback-Leibler functional.

The parameter set \mathcal{P} allows us to predict the ground-state configuration $\mu(S, \mathcal{P})$ and stiffness $K(S, \mathcal{P})$ for any sequence S.

MD vs Model: ground-state configuration

MD vs Model: ground-state configuration S=GCTAT**T**TATATATAGC

MD vs Model: ground-state stiffness S=GCGATCGATCGAGC

Summary

• A model to predict the ground-state configuration and flexibility of B-form DNA from its sequence has been developed.

• The model can resolve sequence-effects both within and between oligomers.

• The model was parametrized using MD and its predictive capabilities have been tested against MD.

• The model provides a way to quantify the intrinsic pre-stress or *frustration* in DNA.

• The model suggests non-local dependence of ground-state on sequence is due to pre-stress.

Thank You
